

Deep learning methods to improve Particle Flow reconstruction

Friday 17 January 2020 14:10 (20 minutes)

Canonical particle flow algorithm tries to estimate neutral energy deposition in calorimeter by first performing a matching between calorimeter deposits and track direction and subsequently subtracting the track momenta from the matched cluster energy deposition. We propose a Deep Learning based method for estimating the energy fraction of individual components for each cell of the calorimeter. We build the dataset by a toy detector (with different resolutions per calorimeter layer) using GEANT and apply image based deep neural network models to regress the fraction of neutral energy per cell of the detector. Comparison of the performance of several different models is carried out.
