

# Charge asymmetry in top-quark pair production at 13 TeV in proton-proton collisions with the ATLAS experiment

*Tuesday, June 25, 2019 9:25 AM (20 minutes)*

We report a measurement of the charge asymmetry in top quark pair production using  $139 \text{ fb}^{-1}$  of proton-proton collision data collected at the centre-of-mass energy of 13 TeV by the ATLAS experiment.

Events are reconstructed in the so-called resolved topology and in a topology with highly boosted top quarks. Both topologies are combined and a fully bayesian unfolding method is used to correct for limited detector acceptance and resolution.

The charge asymmetry is measured inclusively and differentially as a function of the top quark pair mass and longitudinal boost.

The measured values are in good agreement with the Standard Model NLO predictions and a non-zero inclusive asymmetry is observed at a 4 sigma confidence level.
