What we're after:

Distribution of Baryonic Mass within Galaxies

Sheth+S4G collaboration 2010

- Challenge: observations measure light and not mass
 - go **infrared!**
 - dust **extinction** minimal
 - IR luminosity is dominated by **old stars** - the best marker of the distribution of stellar mass in galaxies.

Specific objective:

Establish what the distribution of stellar mass content is in stellar structures in galaxies (e.g., bulge, disk, bars) — using 2D decomposition

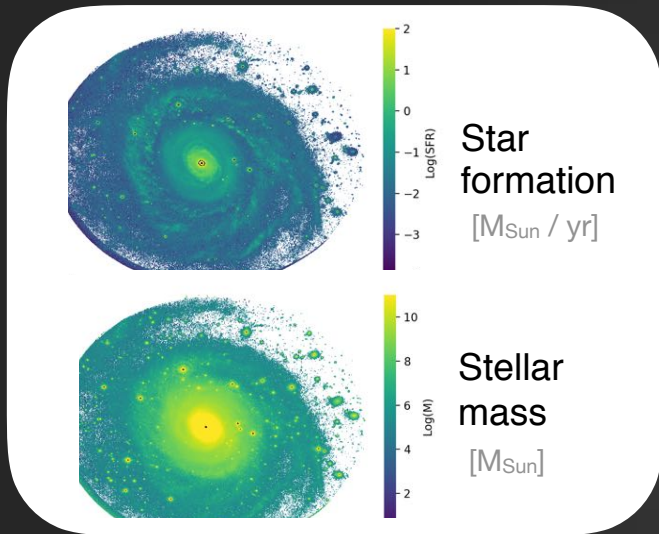

- **Spitzer Survey of Stellar Structures in Galaxies (S4G):** a volume-, mag-, size- limited survey of >2300 nearby galaxies @ 3.6/4.5 μm ($d < 40$ Mpc, $m_B < 15.5$, $D_{25} > 1'$)
 - low surface densities not achievable from the ground: $\Sigma_* \ll 1 M_\odot \text{pc}^{-2}$!
- ➔ **Largest, deepest** (~ 27 mag arcsec 2), **most homogeneous survey of nearby galaxies in the mid-IR**
<http://irsa.ipac.caltech.edu/data/SPITZER/S4G/>
- **3.6 and 4.5 μm** – excellent tracers of stellar mass distribution
 - Effect of dust extinction is negligible
 - Still, **contaminated by young stellar populations**
- ➔ **To convert from light distribution to mass maps, need spatially-resolved analysis of stellar ages.**

What we need:

Convert light to (stellar) mass maps

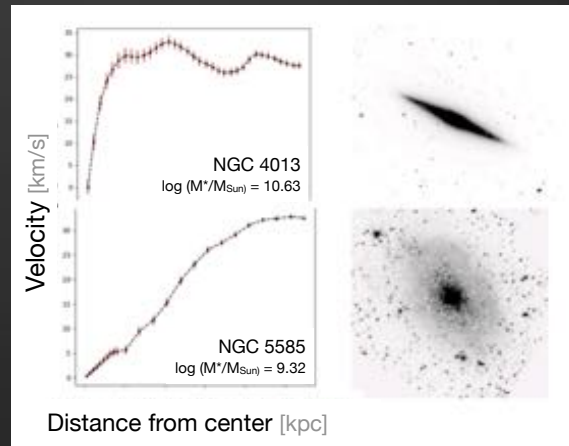

- Deep imaging (to match S⁴G stellar surface densities) with Goodman on SOAR telescope
- Optical coverage of local-volume galaxies (<40 Mpc) in the South
- Reach equivalent of S4G depth: 1 M_{Sun}/pc²

CANGA:
the largest, deepest, most homogeneous survey of southern galaxies in the optical

Galaxy formation in 2D!!

Census of Austral Nearby Galaxies

[PIs: Menéndez-Delmestre + T. S. Gonçalves]

50 galaxies done
100s to go
STAY TUNED!

Specific objective:

Careful characterization of stars in galaxies to isolate dark matter component in rotation curves — construct a more realistic dark matter halo for our own galaxy and establish restrictions on the local density of dark matter.

➔ optimize predictions in the direct detection of dark matter (e.g., LZ)
