Performance studies of RPC detectors with new environmentally friendly gas mixtures in presence of LHC-like radiation background

R. Guida, B. Mandelli, *G. Rigoletti*

CERN

Université Claude Bernard Lyon I

15th Topical Seminar on Innovative Particle and Radiation Detectors
(IPRD19) 14-17 October 2019   Siena, Italy

Outline

Overview on the Resistive Plate Chambers ***gas mixtures*** and possible alternatives

Characterization of RPCs with new eco-friendly gas mixtures

RPC ***operation*** with new environmentally friendly gas mixtures at CERN Gamma Irradiation Facility (GIF++)

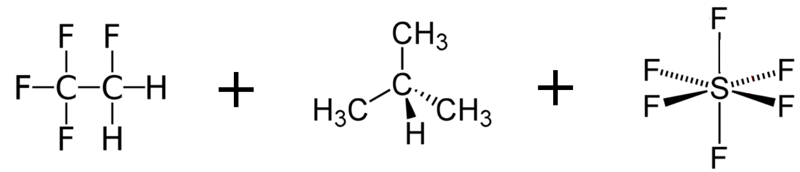
Greenhouse Gases in RPC operation

RPC gas mixture at LHC

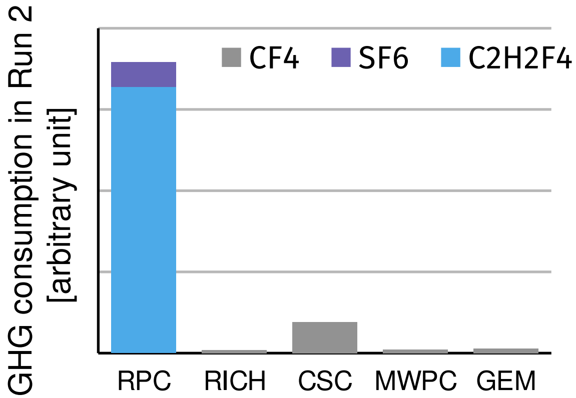
→ Made out of **three** components

→ **High Global Warming Potential** due to presence of *SF6* and *R134a*

~95% | 4-5% | 0.3%



GWP 1430 | GWP 3.3 | GWP 22800



GHG emissions

→ The **main** contribution is from ***R134a***

→ *R134a* and *SF6* due to ***leaks*** at ***detector level*** at ATLAS and CMS RPCs

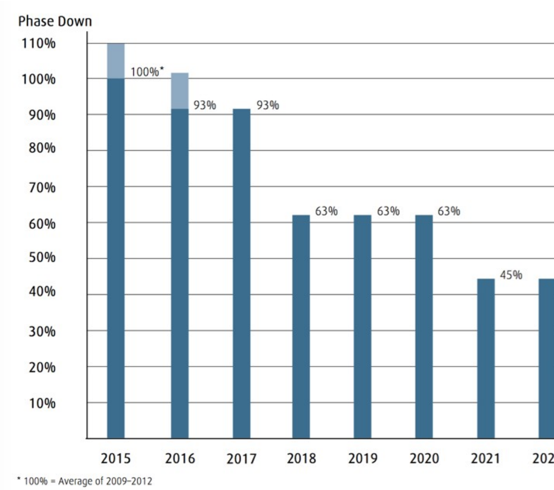
→ A campaign of ***leaks reparation*** is currently ongoing

European Union F- regulation

→ **Limit the total amount** of F- gases that can be sold → Phase down process

→ **Banning the use of F- gases** where eco friendly alternatives are present

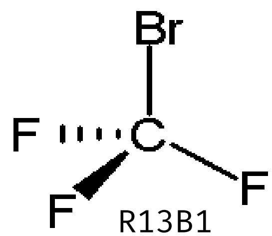
→ **Preventing emissions** by requiring proper checks and servicing of the gasesand recovery of the gases



HFC phase down schedule *by Linde Group*

RPC gas mixtures

First gas mixtures for RPCs were Ar and/or R13B1

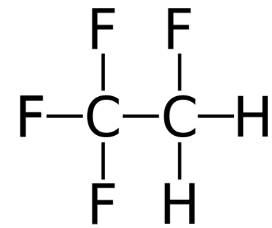


R13B1

(CBrF3)

GWP 6900 - ODP 10

R13B1 was then replaced with R134a + small quantities of iC4H10 and SF6



R134a

($C_2H_2F_4$)

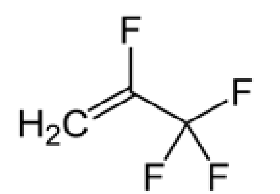
GWP 1430 - ODP 0

Refrigerant industry **started using HFO** gases as replacement of R134a

Hydro-Fluoro-Olefin (HFO)

- Contains C=C bound
- Contains Fluorine
- Contains Hydrogen

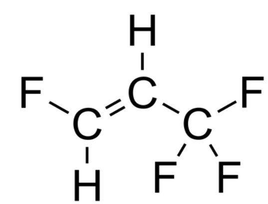
Thermodynamical** characteristics **are known** for HFOs but studies on **ionization properties** have **just started



HFO-1234yf (flam)

($C_3H_2F_4$)

GWP 4



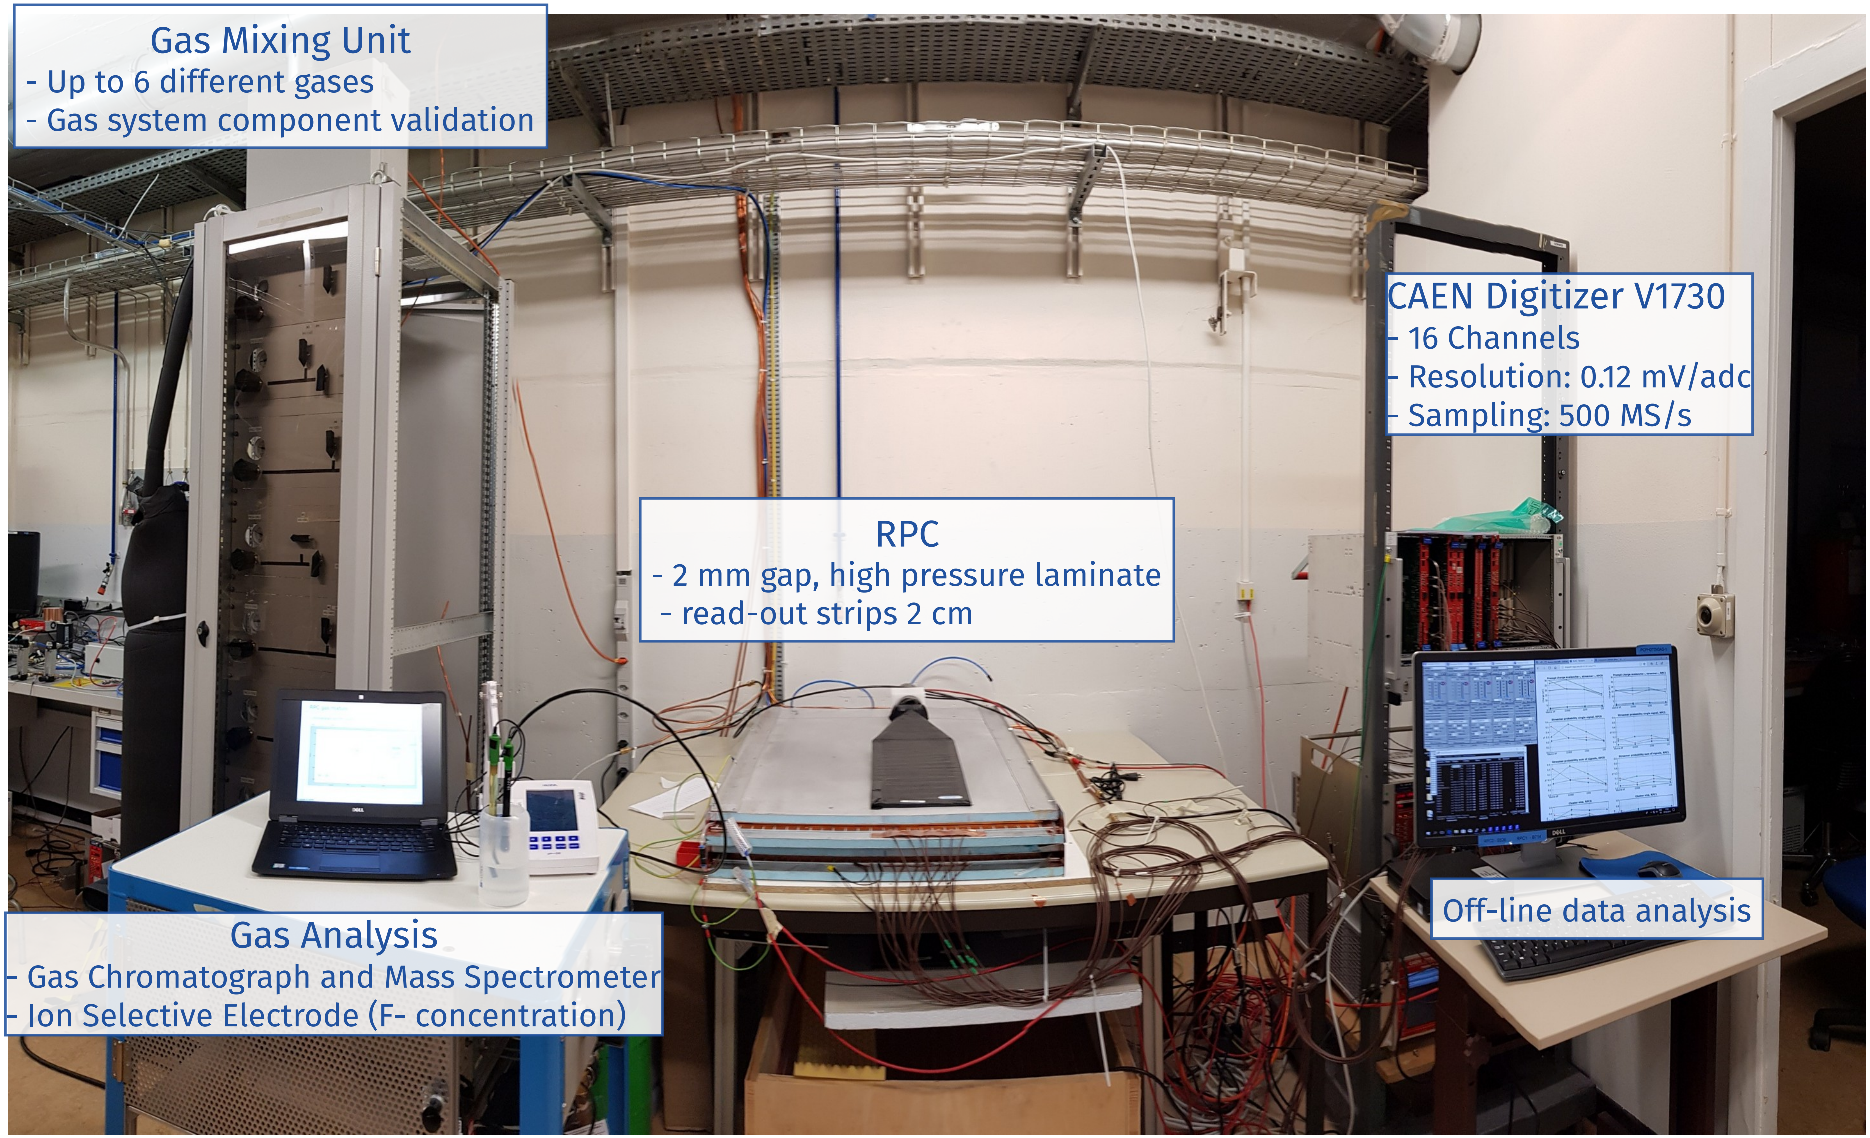
HFO-1234ze

($C_3H_2F_4$)

GWP 6

Goal: find and eco-friendly gas mixture compatible with the current ATLAS and CMS RPC systems (i.e. requires no change in the HV cables, FE electronics, gas system etc.)

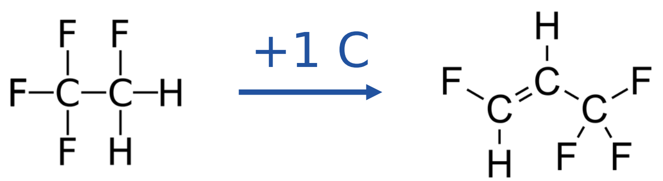
Experimental setup for cosmic muons



HFO based gas mixtures

Initially, R134a was completely replaced by HFO

- Results indicate **higher working voltage** (>12kV) → Related to C=C bound
- **Avalanche signals smaller compared** to Standard Gas Mixture



An addition of a gas to lower the working point is required

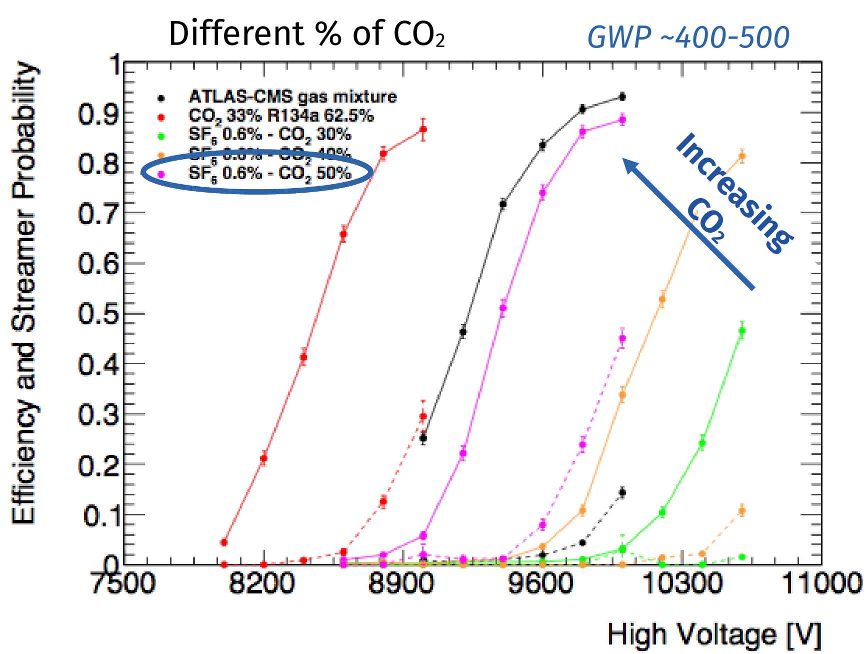
- **Promising results** with +20-30% of ***He***

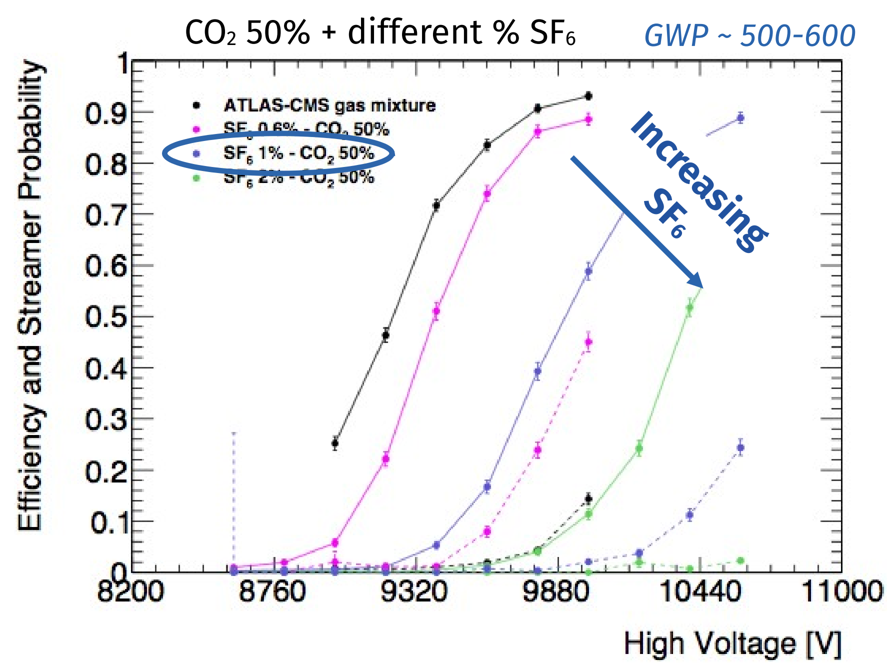
  The use of He + presence of leaks may affect LHC operation

- Use of ***CO_2*** as inert gas: +10 % CO_2 → - 800V

  The streamer probability increases → CO_2 different quenching properties w.r.t. to iC_4H_{10}

  Need to keep a ***small amount of R134a*** and increase ***SF_6*** concentration





Selected HFO based gas mixtures

Over 50 different gas mixtures tested

Tested 3, 4 and **5 components** gas mixtures

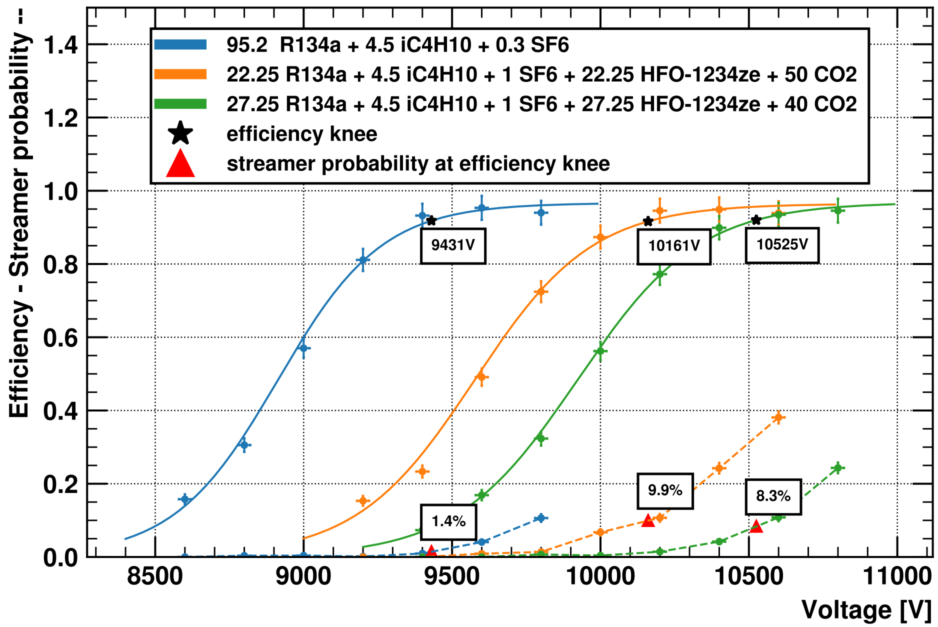
HFO based gas mixture

Performed best together with ***CO_2*** and ***R134a***

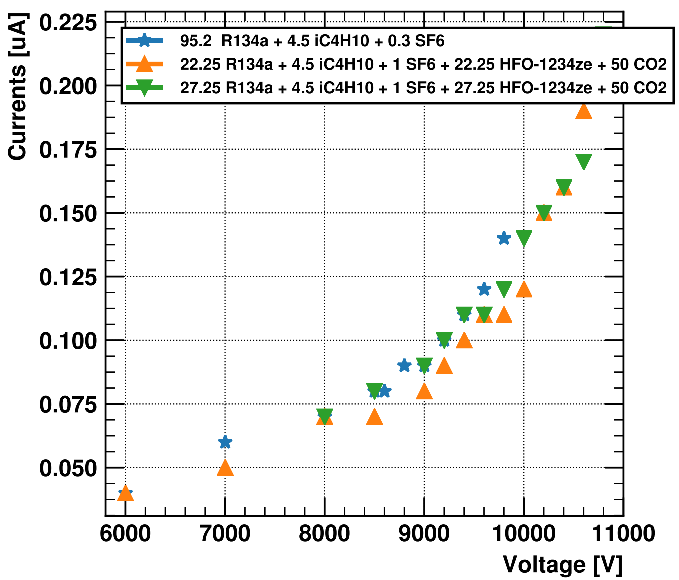
HFO + CO_2 + R134a + 4.5% iC_4H_{10} + 1% SF_6

Fine tuning of HFO gas mixtures

Two candidates that can compete with the standard gas mixture



Gas mixture	GWP	Knee (95% effmax) [V]	Streamer probability %	Avalanche/ Streamer charge [pC]	ΔV(eff-str)
Standard gas mixture	1430	9450	1.4	0.90/8.7	1000
HFO + 50% CO_2	550	10150	9.9	1.35/17.1	950
HFO + 40% CO_2	620	10550	8.3	1.20/16.3	980



CERN Gamma Irradiation Facility (GIF++)

*Goal: study **RPC performance** with **muon beam**, **gamma background** and **HFO** based gas mixtures*

GIF++ facility

- Located along SPS line, north area
- Built to emulate the background conditions of LHC

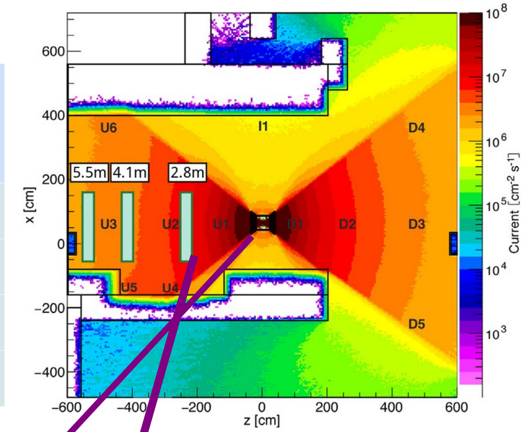
→ Gamma Source

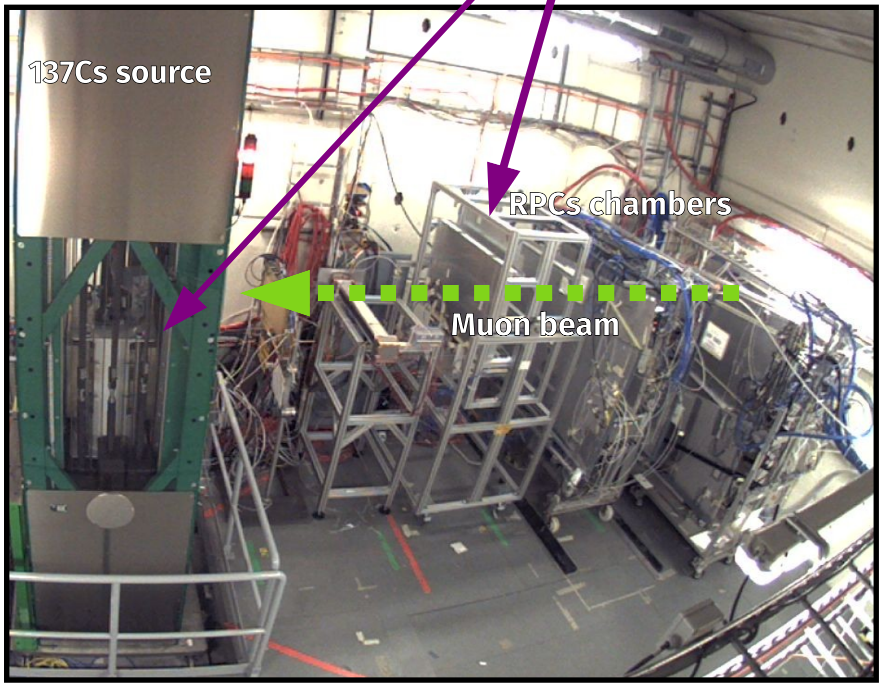
^{137}Cs of 14 TBq → 662 KeV gamma peak background

→ Muon Beam

100 GeV, 10^4 muons/spill, 10x10 cm^2 area

ABS	Gamma Rate [kHz/cm²]
100	55.3
220	41.2
2200	3.75
22000	0.774

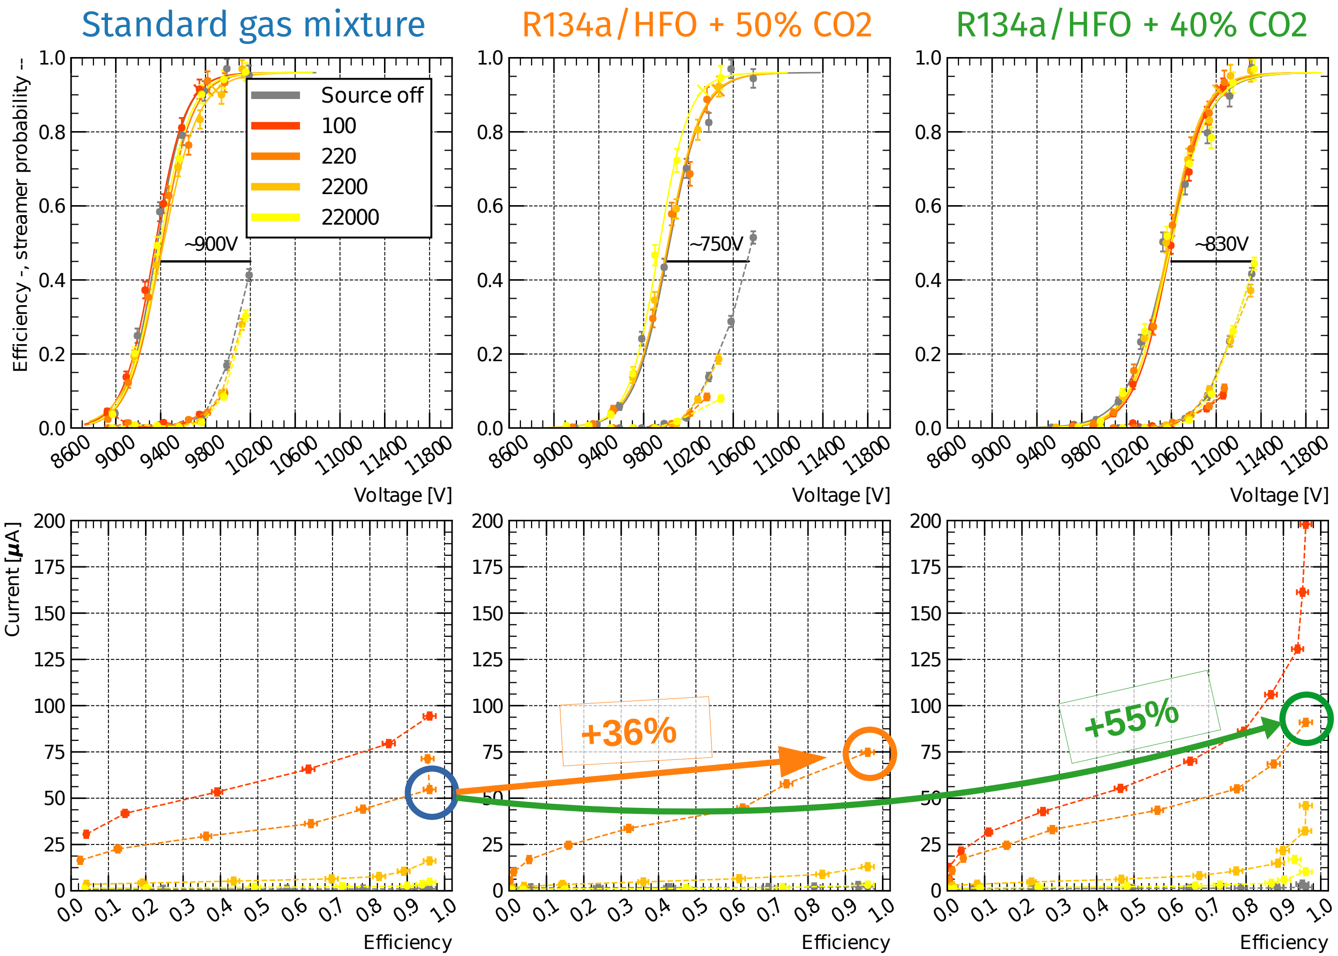




Setup DAQ and DCS

- Raw waveform acquisition via v1730 digitizer
- HV control via dcs
- Online monitoring of gas parameters via influxdb + grafana
- EOS storage of data
- Offline analysis python + pandas + numpy on SWAN

Muon efficiency vs. currents



Streamer probability at ABS 220 (counting rate ~ 250 Hz/cm²)

Gas mixture	At HV knee	At efficiency (+150 V)
Standard gas mixture	3%	13%
HFO + 40% CO_2	8%	25%
HFO + 50% CO_2	15%	23%

+10%

Streamer probability is 10% higher at working point

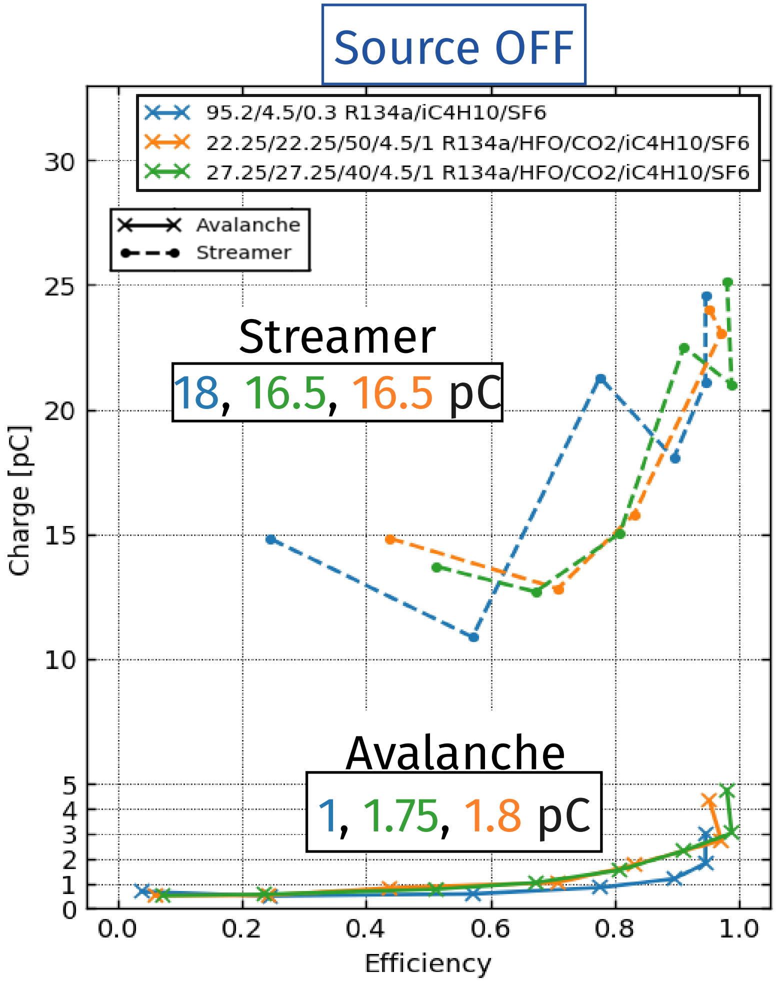
→Efficiency curves are plotted against **effective voltage** seen by **gas gap** ($HV_{eff} = HV_{app} - RI$)

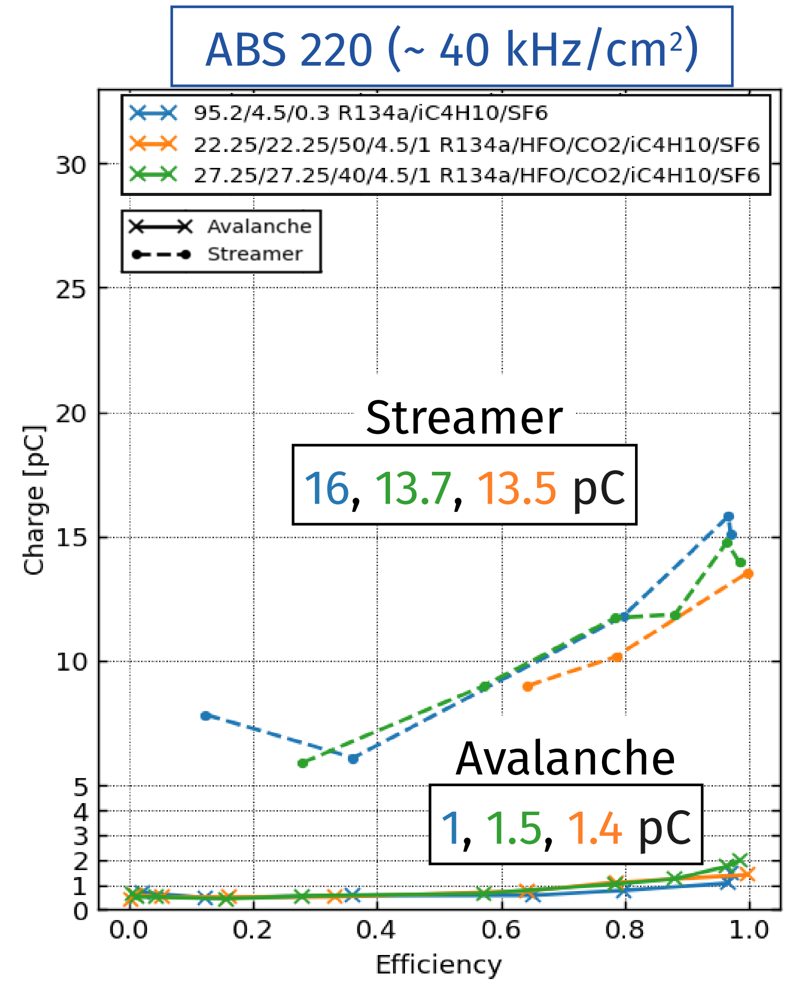
→Data is fitted with a **sigmoid** → Information about **maximum efficiency** and **knee**

→**Currents raise** of ~20% with a change of 10% of CO_2

→**Δ(eff – str.)** increases when CO_2 decrease

Pulse charge





→ The mean avalanche charge is higher for the eco-friendly gas mixtures

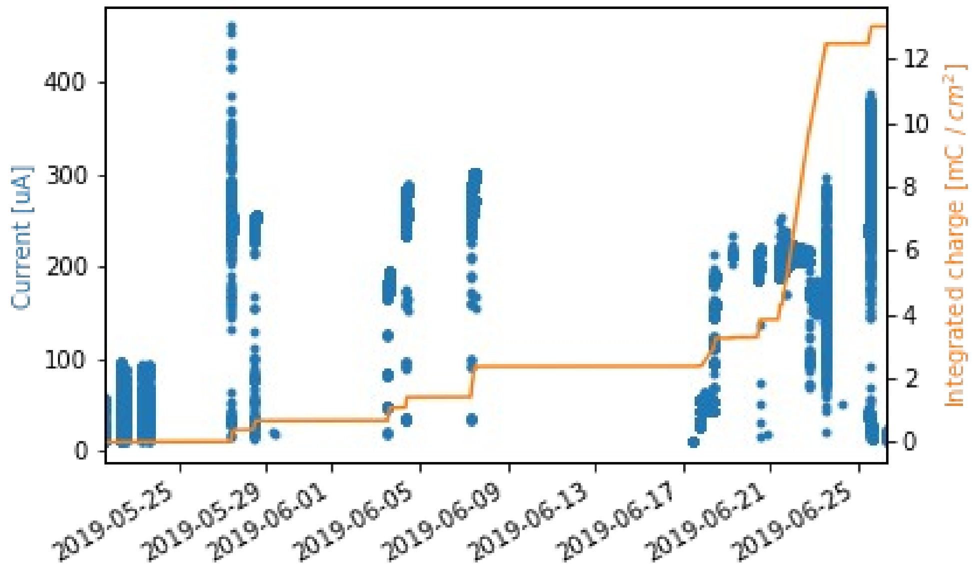
→ The mean streamer charge is lower for the eco-friendly gas mixtures

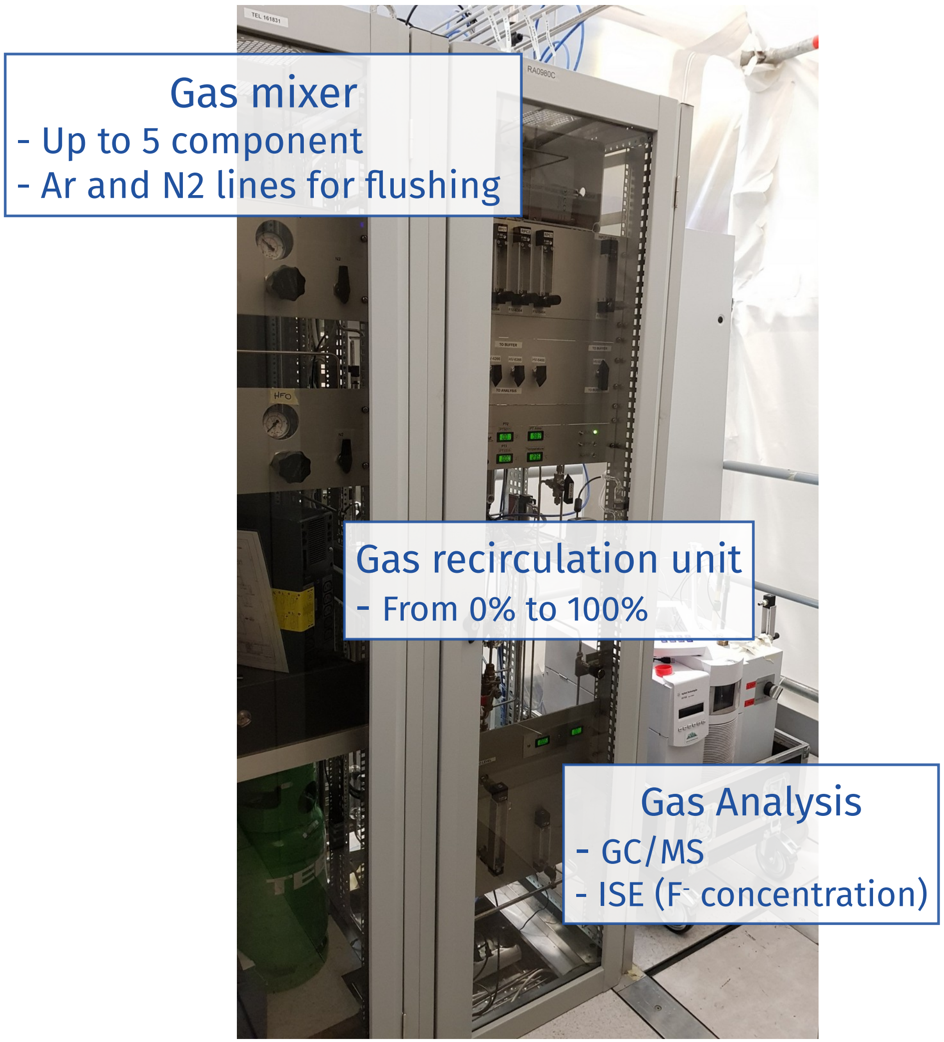
Gas recirculation system

RPC operation must be validated under LHC like conditions → **High background rate** → ***Gas recirculation***

RPCs operated under gas recirculation with eco-friendly gas mixtures
Validation with selected HFO based gas mixture

Cosmics validated
Stable performance, low current
Gamma irradiation validation ongoing
Stable currents, change in detector resistivity observed
Monitoring of currents and integrated charge





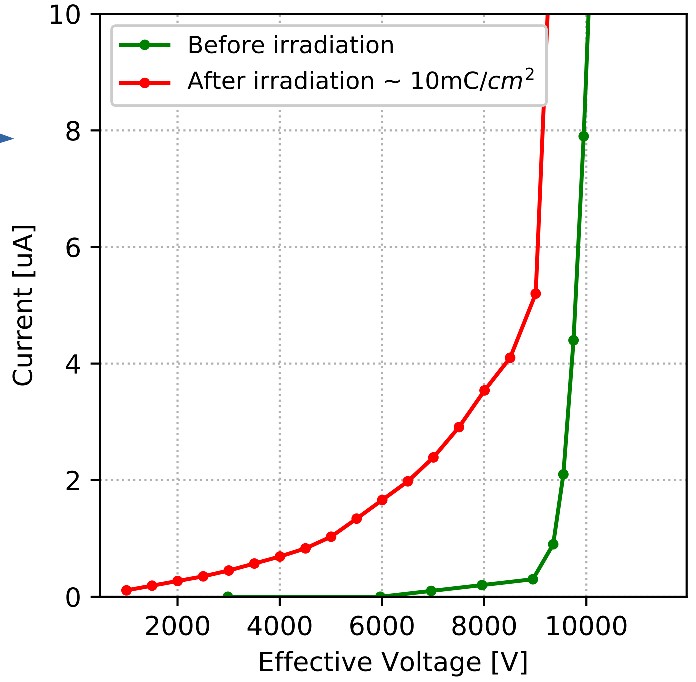
Dark current monitoring

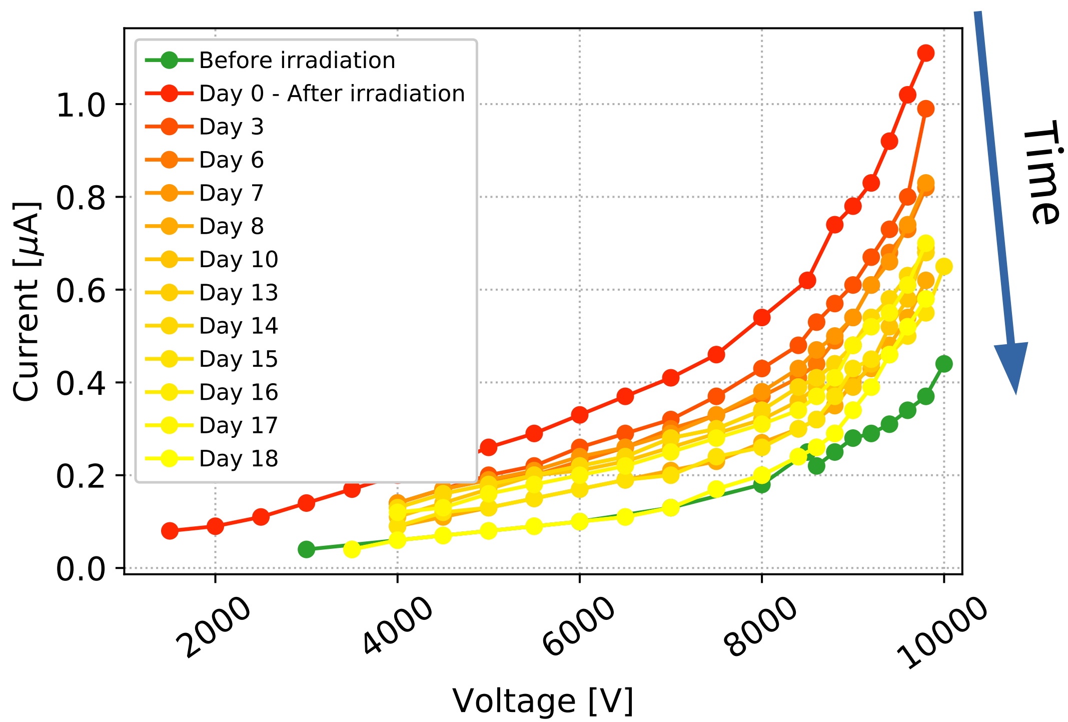
Observed increase of dark currents before and after irradiation

- ~10 mC/cm_2 accumulated

Detector were then flushed with standard gas mixture without irradiation

- Observed a recovery trend
- Dark currents almost back to before irradiation condition





It is important to understand and estimate the impurities accumulated in the detector

Creation of impurities under irradiation

Impurities created from R134a and HFO

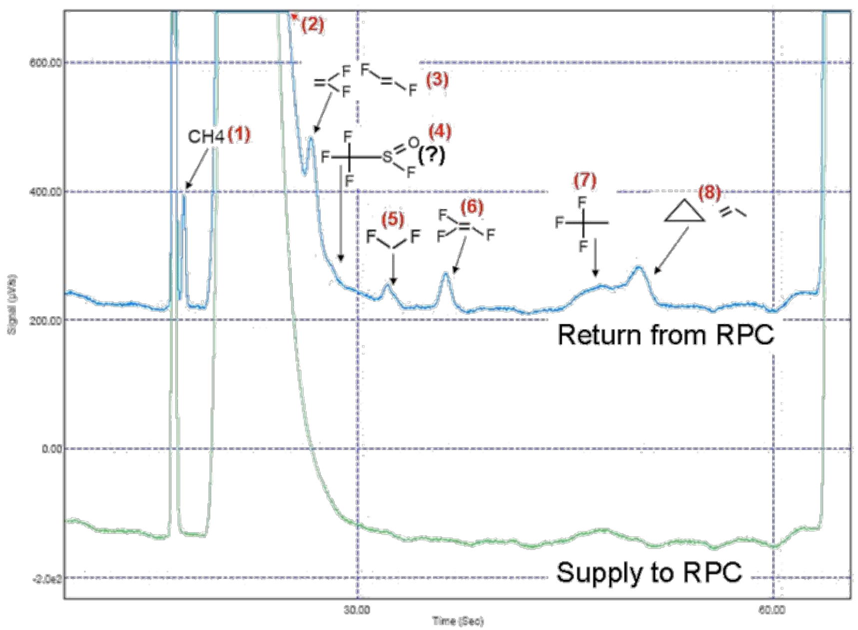
- Under the effect of high background radiation and electric fields Freons molecules break into fluorine radicals
- F- radicals are very reactive, especially with water → HF formation, very aggressive for linseed oil and bakelite
- Sub-products in the order of the ppm
- Accumulation in case of closed loop system

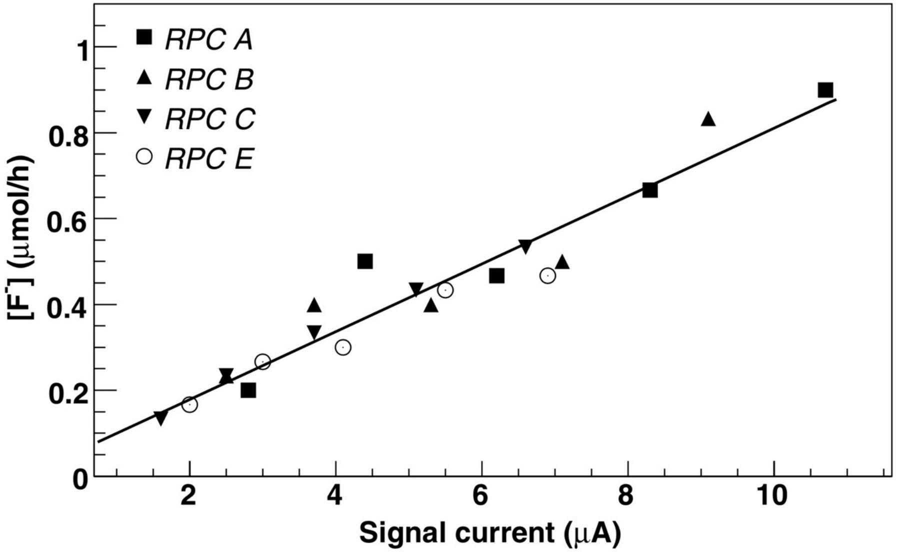
Creation of impurities observed also in RPCs at LHC experiments during Run 2

- Safety limit is still being understood

HFO gases have shorter atmospheric lifetime than R134a

- They could break more easily
- F- production depends on the current of the detector and the prompt charge size





Creation of impurities under irradiation

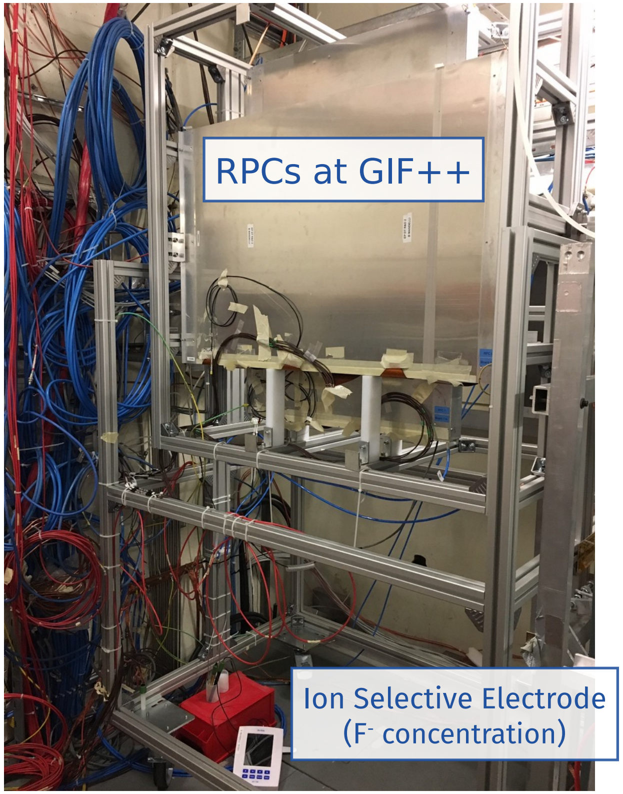
Radiation measurements with HFO based gas mixture

Test performed by irradiating 2 RPCs at different background rates and at different voltages
- Open mode, fixed flow and correction for environmental conditions

Gas mixture tested:
- Standard Gas mixture and selected eco-friendly
- Comparison between the production of impurities

Impurities measured with different instruments
- Gas Chromatographer / Mass spectrometer
- Ion Selective Electrodes (ISE) for F- measurements

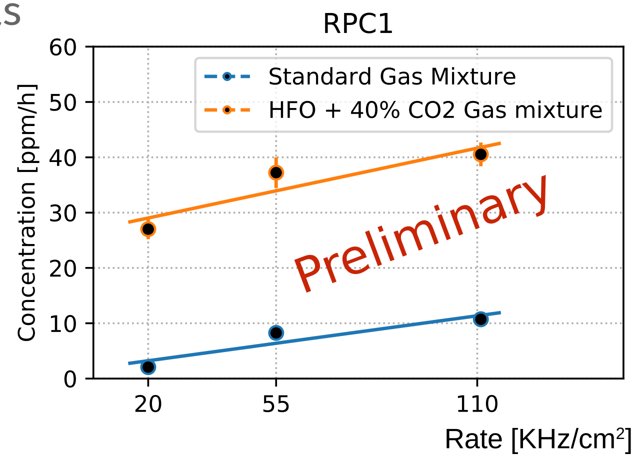
At detector efficiency
- The production depends on the background rate
- The F- production of the selected eco-friendly gas mixture is ~4 times higher than the standard gas mixture



Assuming contribution from SF6 neglectable

↓

HFO is breaking ~10 times more easily than R134a



Mixture	F- rate production	Contribution on to the mixture
95.2% R134a	10ppm/h	R134a = 10.5ppm/h
27.25% R134 27.25% HFO	40ppm/	HFO = 136ppm/h

Conclusions

R&D goal: find an eco-friendly gas mixture compatible with the current ATLAS and CMS RPC systems

Eco friendly gas mixture for RPCs

- HFO not suitable for direct substitution to R134a
- HFO requires an inert gas to work at lower working points (<12 kV)

Characterization of RPCs with eco-friendly gas mixtures

- More than 50 different gas mixture tested
- HFO + He or CO_2 shows similar properties to the standard gas mixture

RPCs operation with eco-friendly gas mixtures under background irradiation

- RPC tested up to HL-LHC expected rate (~300 Hz/cm^2 counting rate)
- Streamer probability and currents are slightly higher for HFO based gas mixtures
- Long term performance studies of eco-friendly mixture are currenly going on
- HFO seems to break more easily to R134a: studies ongoing on the causes and possible solutions

Thank you

Recirculation system
