

VBF Jet Isolation Studies

Danny Noonan, James Bueghly, Jim Hirschauer, Nate Odell,
[Uttiya Sarkar](#)

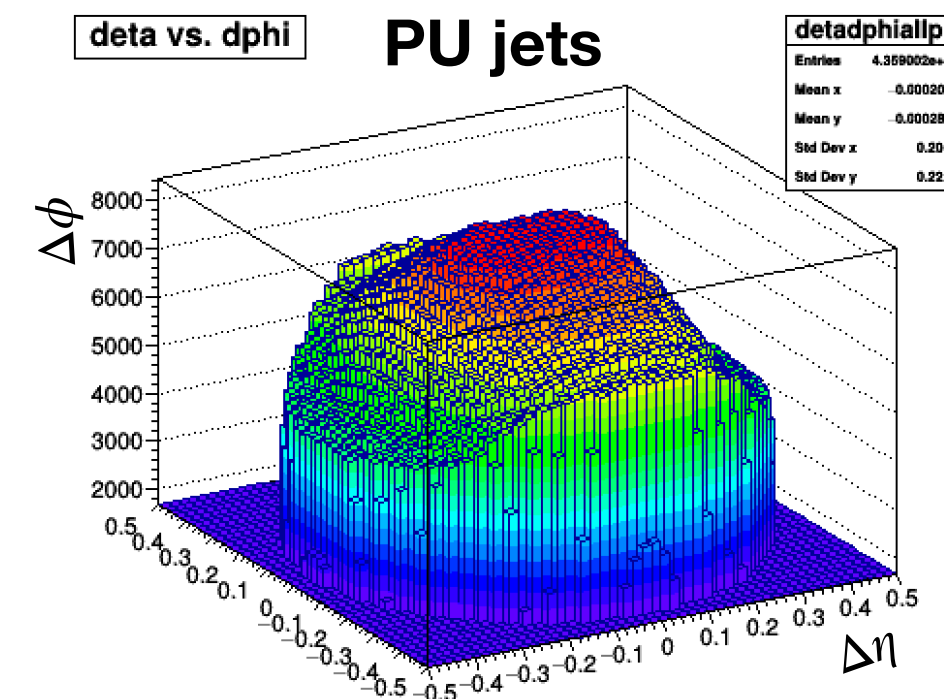

Overview

- We want to construct an algorithm for HGICAL to distinguish the VBF jets from Pile-Up (PU) jets
- VBF jets tend to be narrower than gluon jets which is the primary motivation of the study
- We want to use this idea to characterize Non-PU from PU jets and separate them at trigger level

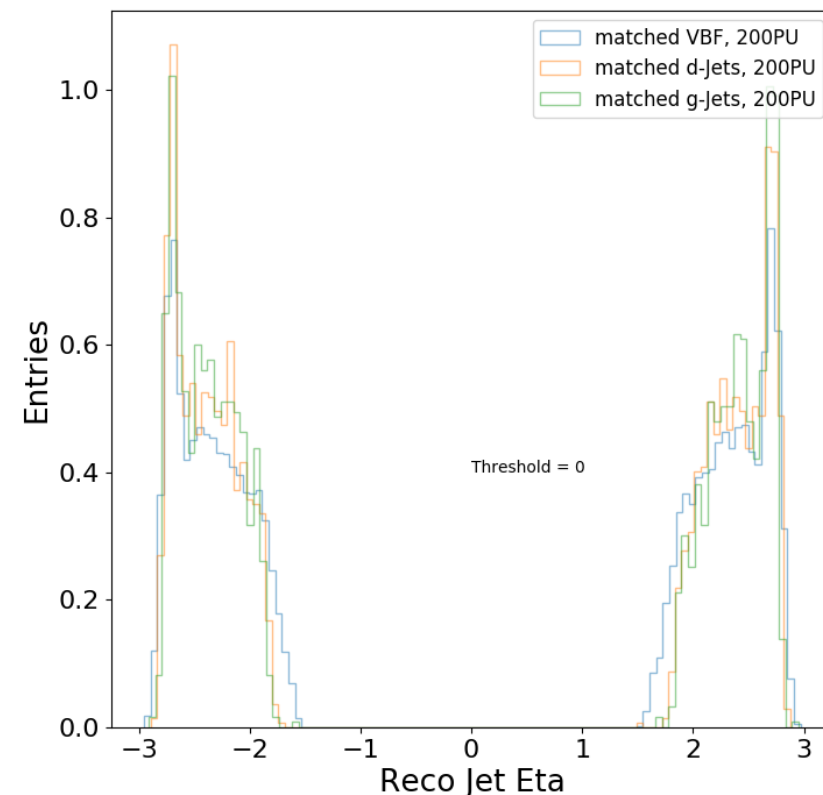

VBF 200PU

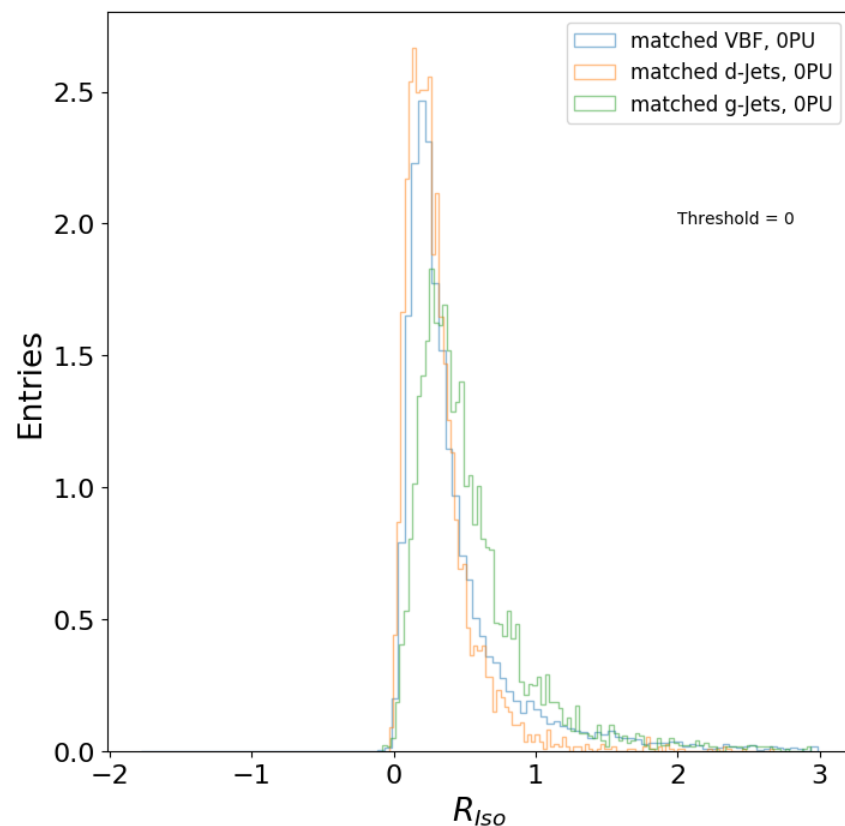

Jet Reconstruction and Requirements

- We cluster the final state trigger cells with algorithm using and with a cone radius, Minimum threshold on clustered jet $P_t = 20$ GeV
- We looked at:
 - VBF jets: produced from VBF event using pythia8, for both 0PU and 200PU
 - Particle guns: d-jets and g-jets, produced where there are two back-to-back gen partons going at $p_T = 50$ GeV/200 GeV
- To identify a VBF jet from all the final state jets, we do a matching of jets to the generated partons that are within $dR=0.1$

Jet Reconstruction & Isolation Metric

- We look at the pt distribution of trigger cells along clustered jet radius (for particle guns)
- Divide the jet area into three regions:
 - A: $R < 0.1$
 - B: $0.1 < R < 0.2$
 - C: $R > 0.4$
- Assume a uniform distribution of PU jets, the pt sum scaled to area from C measures the PU pt
- **Definition of R_{iso} is the idea borrowed from Owen Long (UC Riverside)**

Ratio of energy in B over energy in A.

$$R_{iso} = \frac{\sum B - (3/12) \sum C}{\sum A - (1/12) \sum C}$$

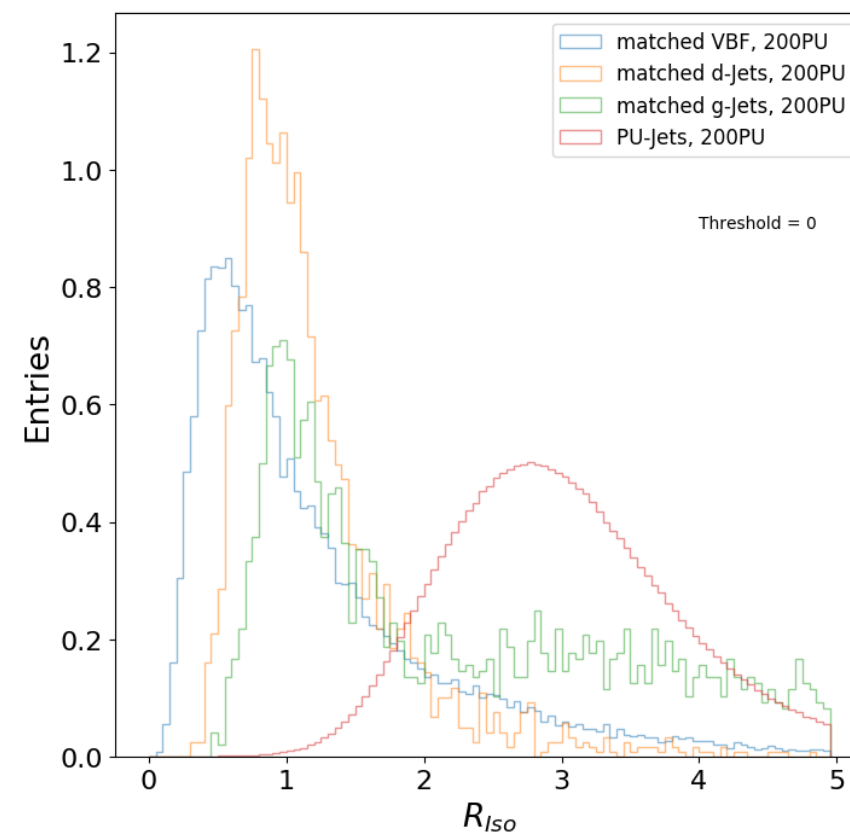

Isolation Metric with and without PU subtraction

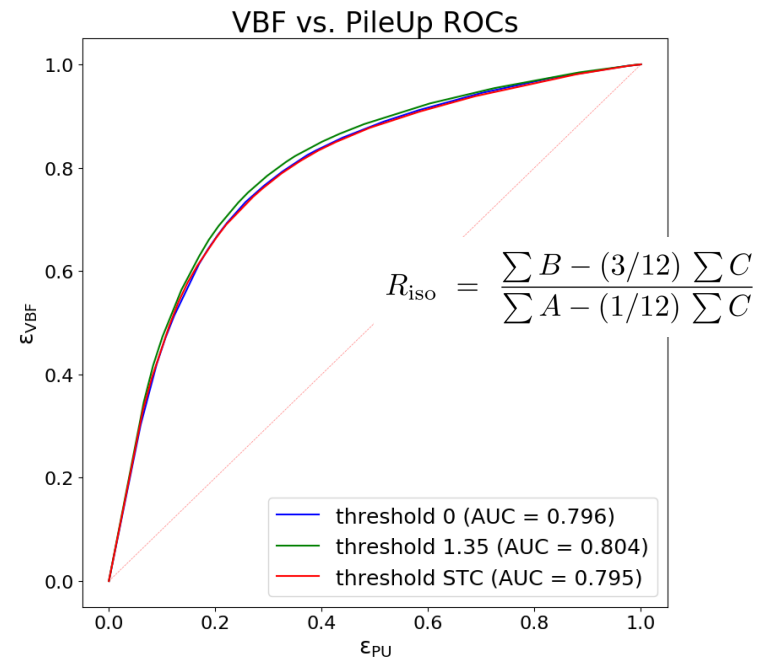

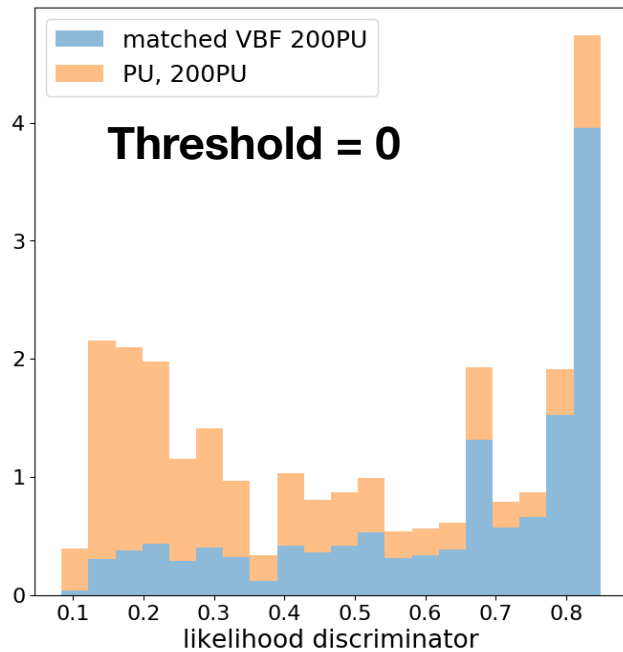

- For 200 PU scenario, we see a large contamination due to PU, for the isolation ratio definition

- If we do not perform any PU subtraction, we see a better discriminating power of R_{iso} with the following definition

$$R_{iso} = \frac{\sum B}{\sum A}$$

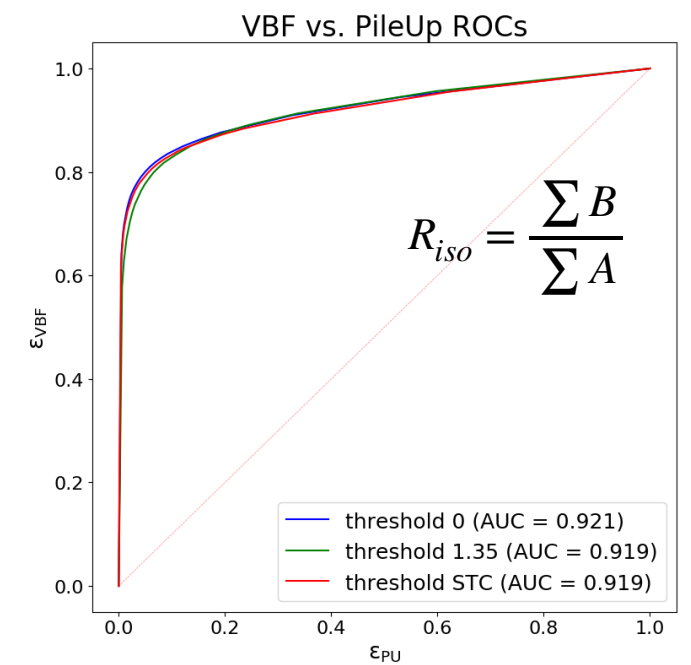

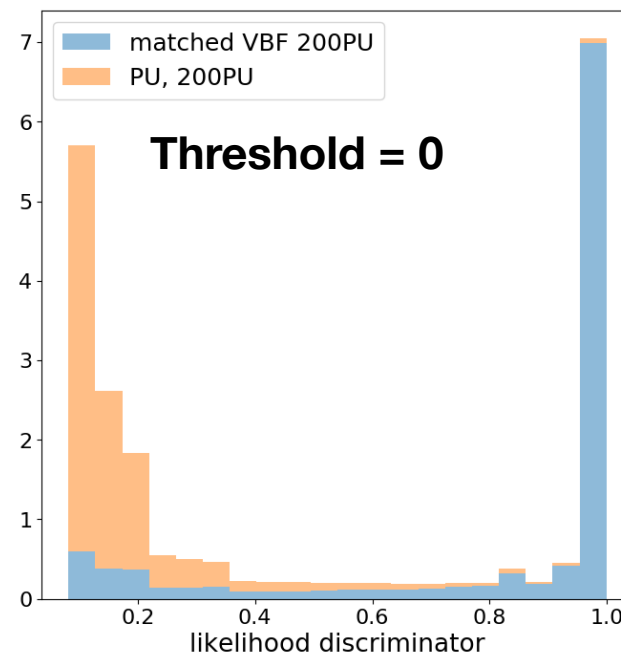

Discriminant and ROC

- Likelihood discriminant is defined by taking the sig/sig+bkg. bin by bin
- From the likelihood, we compute ROC, by taking VBF as signal and PU as background
- With PU subtraction, we see poor discrimination power as compare to the plots below with no PU subtraction

- ~10% improvement in the ROC, when R_{iso} is defined without any PU subtraction

Summary

- We have a preliminary discriminating power of of the isolation ratio and the results look encouraging
- We are checking with particle gun samples (some of the studies in backup) and the likelihood discriminators and also with different trigger selections like mipt and STC

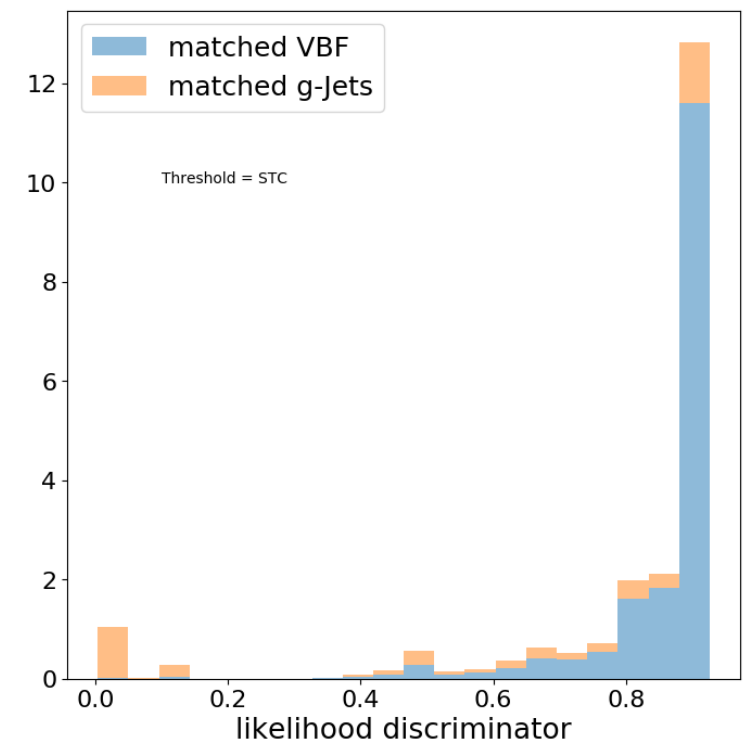

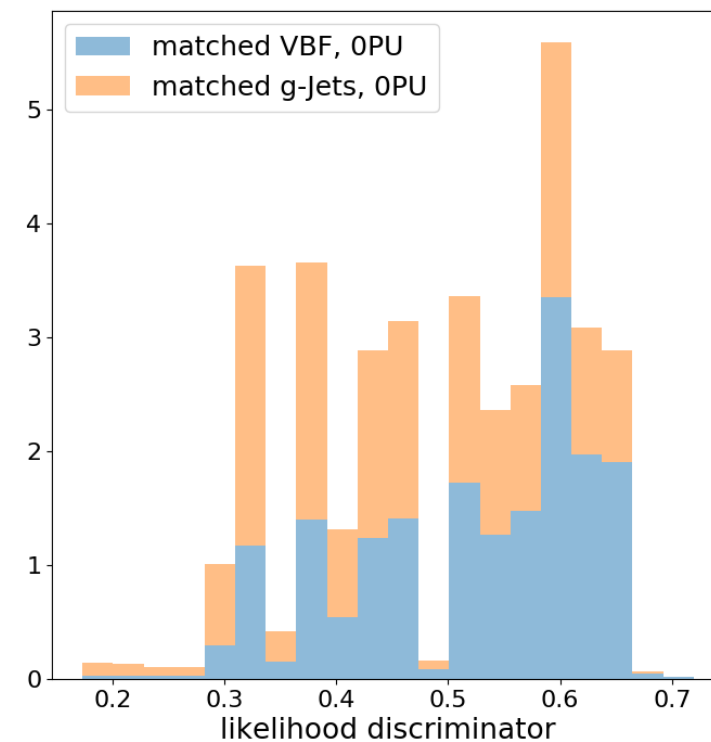

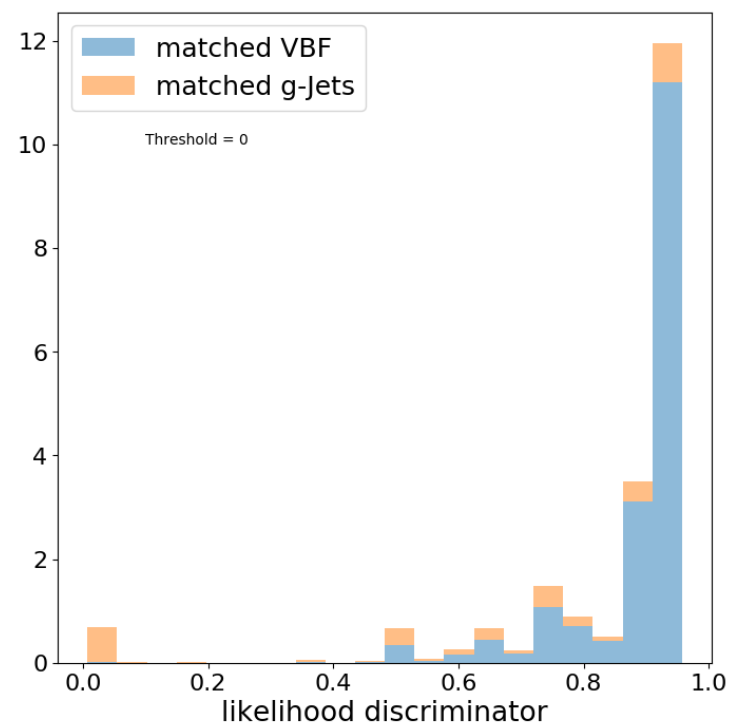

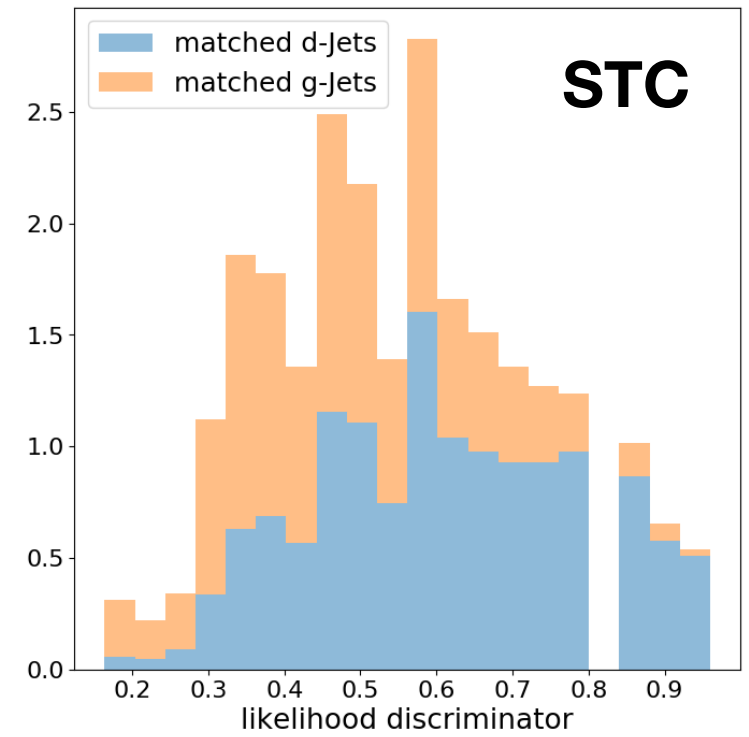

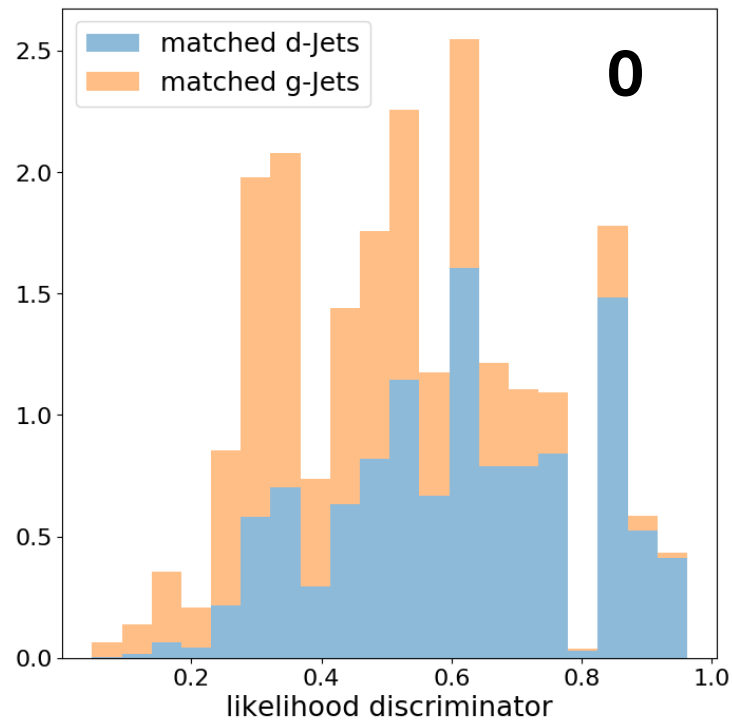

BACKUP0 PU Isolation

$$R_{Iso} = \frac{B - \frac{3}{12}C}{A - \frac{1}{12}C}$$
