SN cosmology: Most direct evidence for an accelerating universe

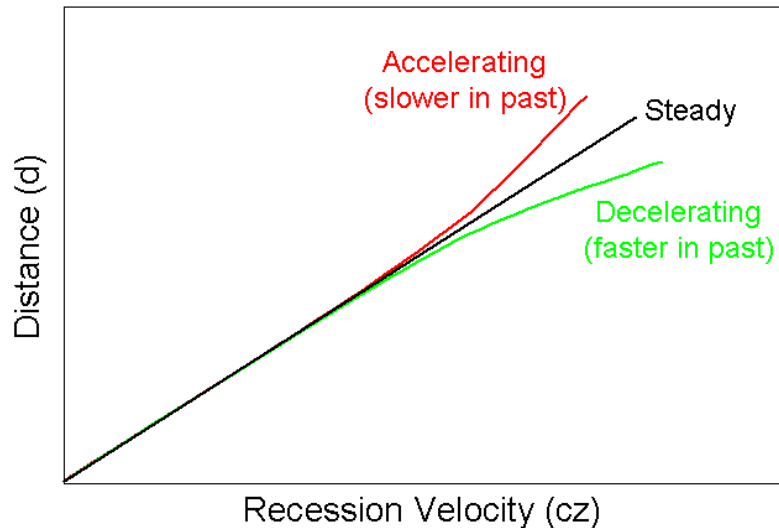

“SN cosmology is the most straightforward tool for studying cosmic acceleration...”

(Weinberg, Eisenstein, Riess et al. 2013)

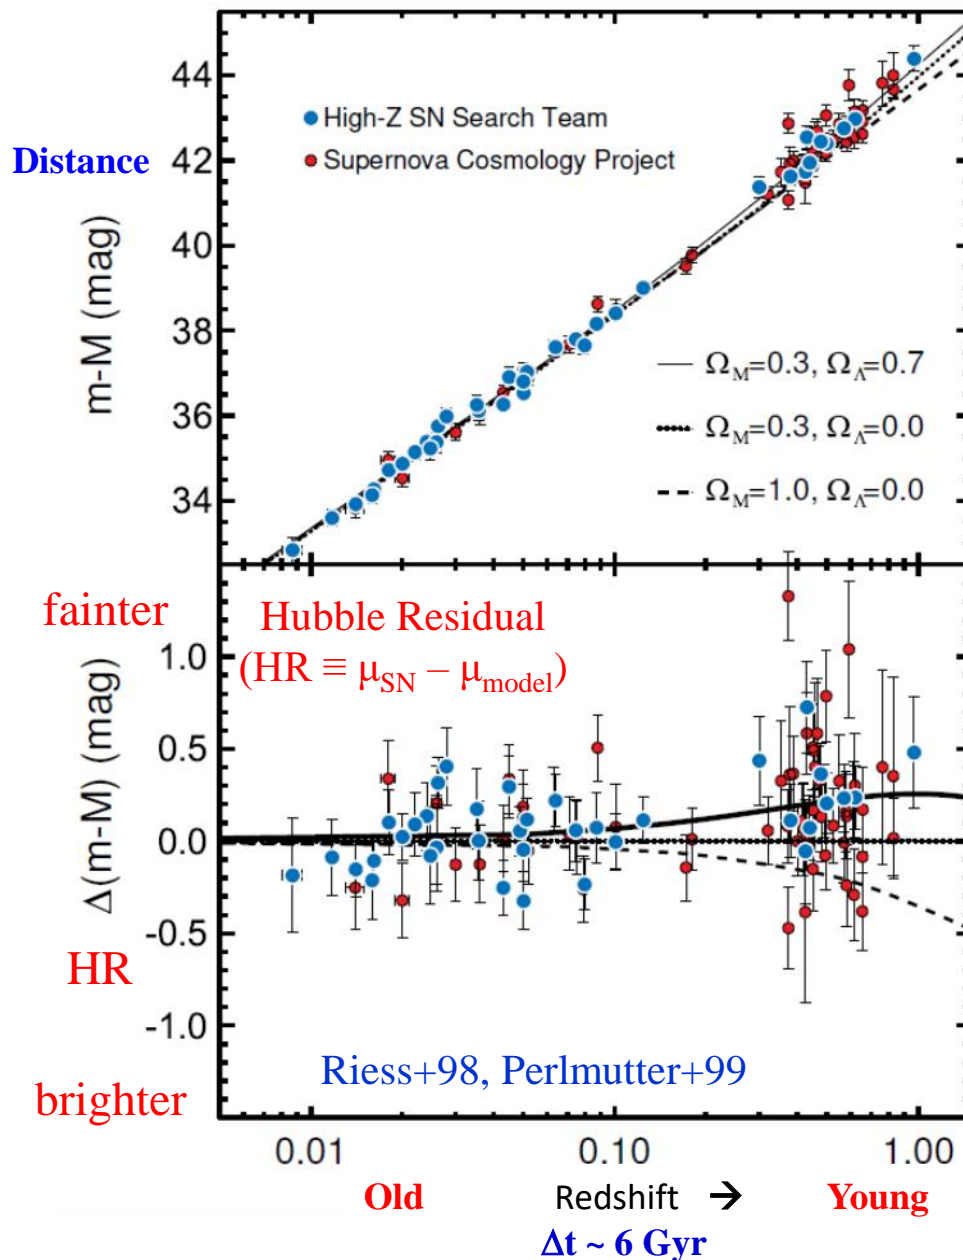

“Independent of GR and based solely upon the SN Hubble diagram...”

(Frieman, Turner, & Huterer 2008, ARAA; Shapiro & Turner 2006; Daly et al. 2008).

CMB provides crucial constraints on the geometry of the universe, “but it alone provides relatively weak constraints on dark energy.” (Planck Collaboration 2020; Frieman et al. 2008)

Accelerating Universe **or** Luminosity Evolution?

Hubble's mistake discovered by Baade

THE RESOLUTION OF MESSIER 32, NGC 205, AND THE
REGION OF THE ANDROMEDA NEBULA

W. BAADE

Mount Wilson Observatory

Received April 27, 1944

ABSTRACT

sensitive plates, taken with the 100-inch telescope, have revealed the companions of the Andromeda nebula—Messier 32 and Messier 205—the nebula itself. The brightest stars in all the companions have a mean color index $+1.3$ mag. Since the absolute photographic magnitude of the brightest stars in the companions is -4.0 mag, the distance to the Andromeda system is 2.5 times that previously determined by Hubble.

Diagram of the stars in the early-type nebulae shows that the globular clusters. This leads to two distinct groups, one representing the neighborhood (the slow-moving stars), the other (type I) are highly luminous O and B stars. The period Cepheids and globular clusters are of type II. Both types seem to coexist in the same region.

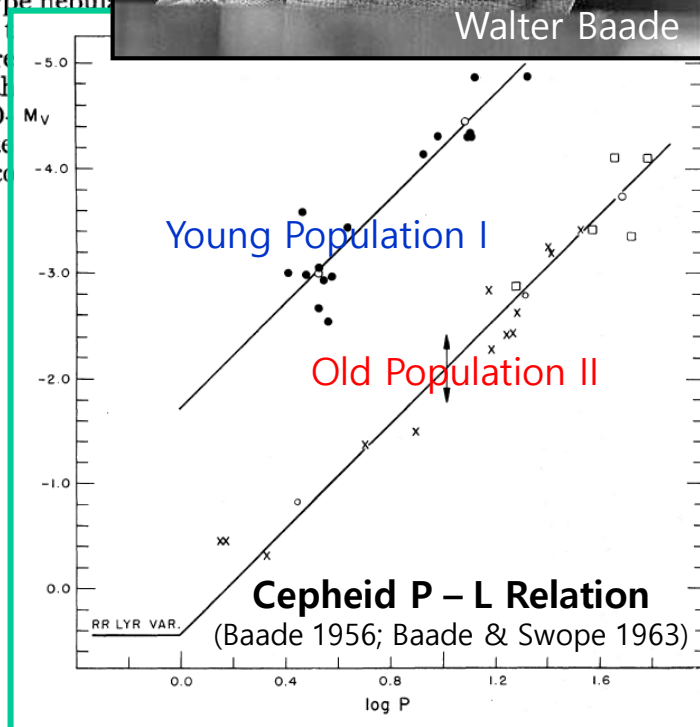

Young population I Cepheids are ~ 1.5 mag brighter than old population II counterparts

→ M31 distance increased by a factor of 2

→ H_0 decreased by a factor of 2!

Luminosity of "Standard Candle" can depend on stellar population age (mass)

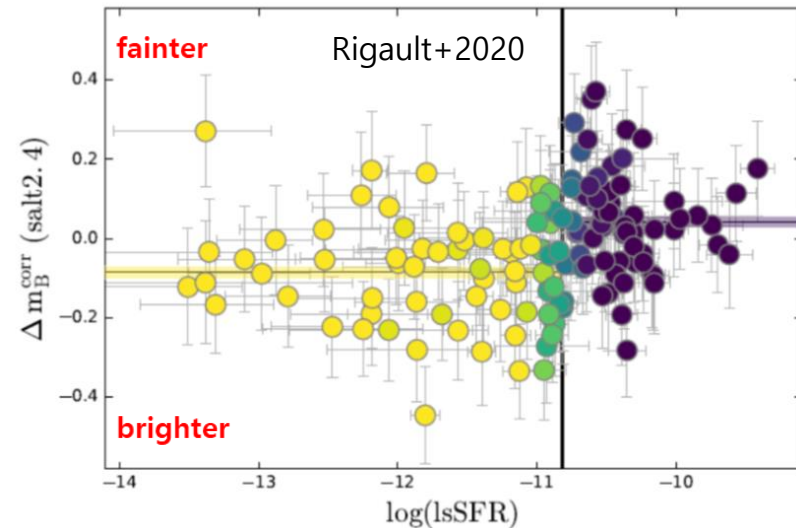

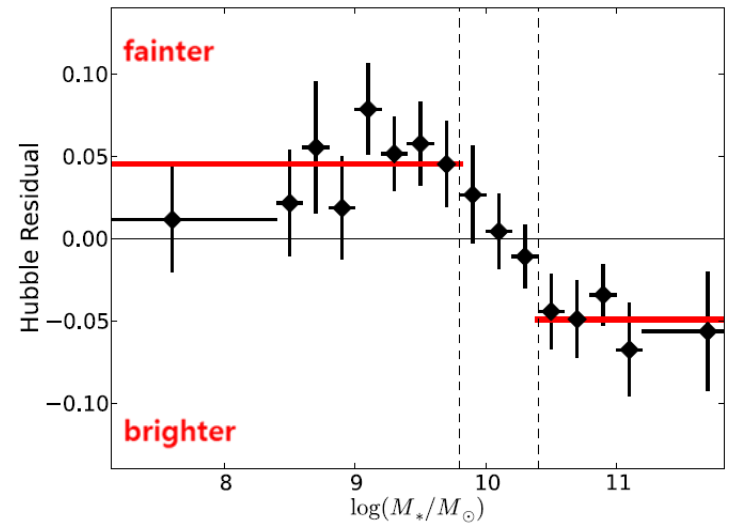

Correlations of SN luminosity (after standardization) with host mass & local SFR

CHILDRRESS ET AL.

1. **SNe Ia in less massive host galaxies are fainter** by ~ 0.1 mag (Sullivan+2010; Kelly+2010; Childress+2013)
2. **SNe Ia in locally star-forming environments are ~ 0.16 mag fainter** than those in passive environments (Rigault+2013, 2020; Kim, Lee+2018)

→ **Most likely due to population age...**
→ Redshift evolution corrections based on these proxies will mislead!

But reliable population age dating for host galaxies was lacking...

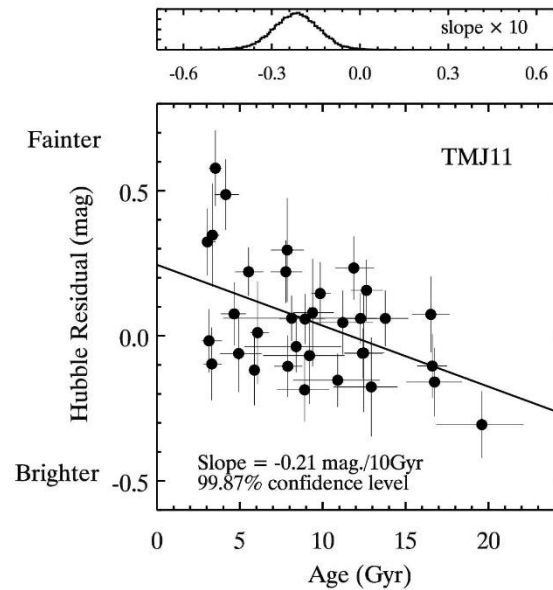

Project YONSEI: Yonsei Nearby Supernovae Evolution Investigation

High Precision ($S/N \sim 175$) Measurement of Early-type Host Galaxy Ages (since 2010)

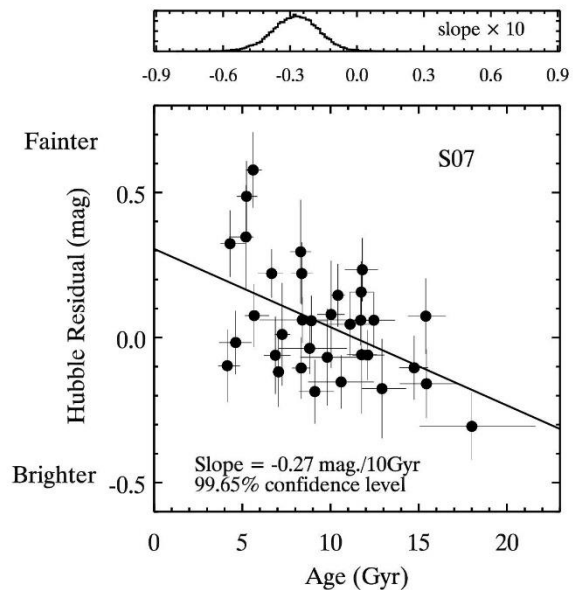

Population Synthesis Models:

Correlation between SN Luminosity & Population Age

After 9 yrs of hard work,
very high S/N (~175)
spectra for ~59 (34) normal
early-type host galaxies
(Abnormal ETGs with emission
lines/recent SF excluded)

3σ Correlation: SNe in younger hosts are
fainter (after standardization)

→ high-z SNe should be similarly fainter

0.051 mag/Gyr

This result is not sensitive to the choice of population
synthesis model

Our result from directly measured ages is consistent with previous investigations based on age proxy (host morphology, host mass, local SFR)

Host Property	Reference	Original Correlation	Direction	Converted to Age difference
Morphology	Hicken et al. (2009)	$\Delta\text{HR} / \Delta\text{morph.}$ $\approx 0.14 \text{ mag} / (\text{Scd/Irr-E/S0})$	Fainter in Later type galaxy	$\sim 0.19 \text{ mag} / 5.3 \text{ Gyr}$ Fainter in Younger galaxy
Mass	Sullivan et al. (2010)	$\Delta\text{HR} / \Delta\text{mass}$ $\approx 0.08 \text{ mag} / (\Delta\log M_{\star} \sim 1)$	Fainter in Less massive galaxy	$\sim 0.21 \text{ mag} / 5.3 \text{ Gyr}$ Fainter in Younger galaxy
Local SFR	Rigault et al. (2018)	$\Delta\text{HR} / \Delta\text{local SFR}$ $\approx 0.16 \text{ mag} / (\Delta\log(\text{sSFR}_{>-10.8} - \text{sSFR}_{<-10.8}, \text{yr}^{-1} \text{ kpc}^{-2}))$	Fainter in Higher SFR environments	$\sim 0.35 \text{ mag} / 5.3 \text{ Gyr}$ Fainter in Younger galaxy
Population Age	This work	$\Delta\text{HR} / \Delta \text{pop. age}$ $\approx 0.051 \text{ mag} / \text{Gyr (YEPS)}$	Fainter in Younger galaxy	$\sim 0.27 \text{ mag} / 5.3 \text{ Gyr}$ Fainter in Younger galaxy

Y. Kang, Y.-W. Lee+2020, ApJ

When they are converted to age difference

based on our result, Scott et al. 2017, & Galbany et al. 2014

→ *They are all pointing to the same direction!*

→ **SNe Ia in younger galaxies (i.e., high-z) are fainter!**

Our result not confirmed from a larger sample of host galaxies of all morphological types??

Evidence for Cosmic Acceleration Is Robust to Observed Correlations between Type Ia Supernova Luminosity and Stellar Age

Abstract

Supernova (SN) cosmology is based on the assumption that the corrected luminosity of SNe Ia would not evolve with redshift. Recently, our age dating of stellar populations in early-type host galaxies (ETGs) from high-quality spectra has shown that this key assumption is most likely in error. It has been argued though that the age–Hubble residual (HR) correlation from ETGs is not confirmed from two independent age data sets measured from multiband optical photometry of host galaxies of all morphological types. Here we show, however, that one of the data sets is based on highly uncertain and inappropriate luminosity-weighted ages derived, in many cases, under serious template mismatch. The other data set employs more reliable mass-weighted ages, but the statistical analysis involved is affected by regression dilution bias, severely underestimating both the slope and significance of the age–HR correlation. Remarkably, when we apply regression analysis with a standard posterior sampling method to this data set comprising a large sample ($N = 102$) of host galaxies, very significant ($>99.99\%$) correlation is obtained between the global population age and HR with the slope ($-0.047 \pm 0.011 \text{ mag Gyr}^{-1}$) highly consistent with our previous spectroscopic result from ETGs. For the local age of the environment around the site of SNe, a similarly significant ($>99.96\%$) correlation is obtained with a steeper slope ($-0.057 \pm 0.016 \text{ mag Gyr}^{-1}$). Therefore, the SN luminosity evolution is strongly supported by the age dating based on multiband optical photometry and can be a serious systematic bias in SN cosmology.

Even the dataset originally used by Rose, Riess+2020 to oppose our claim is instead strongly supporting our result!!

→ 5σ correlation confirmed by a third party (Zhang+2021)

Type Ia SNe

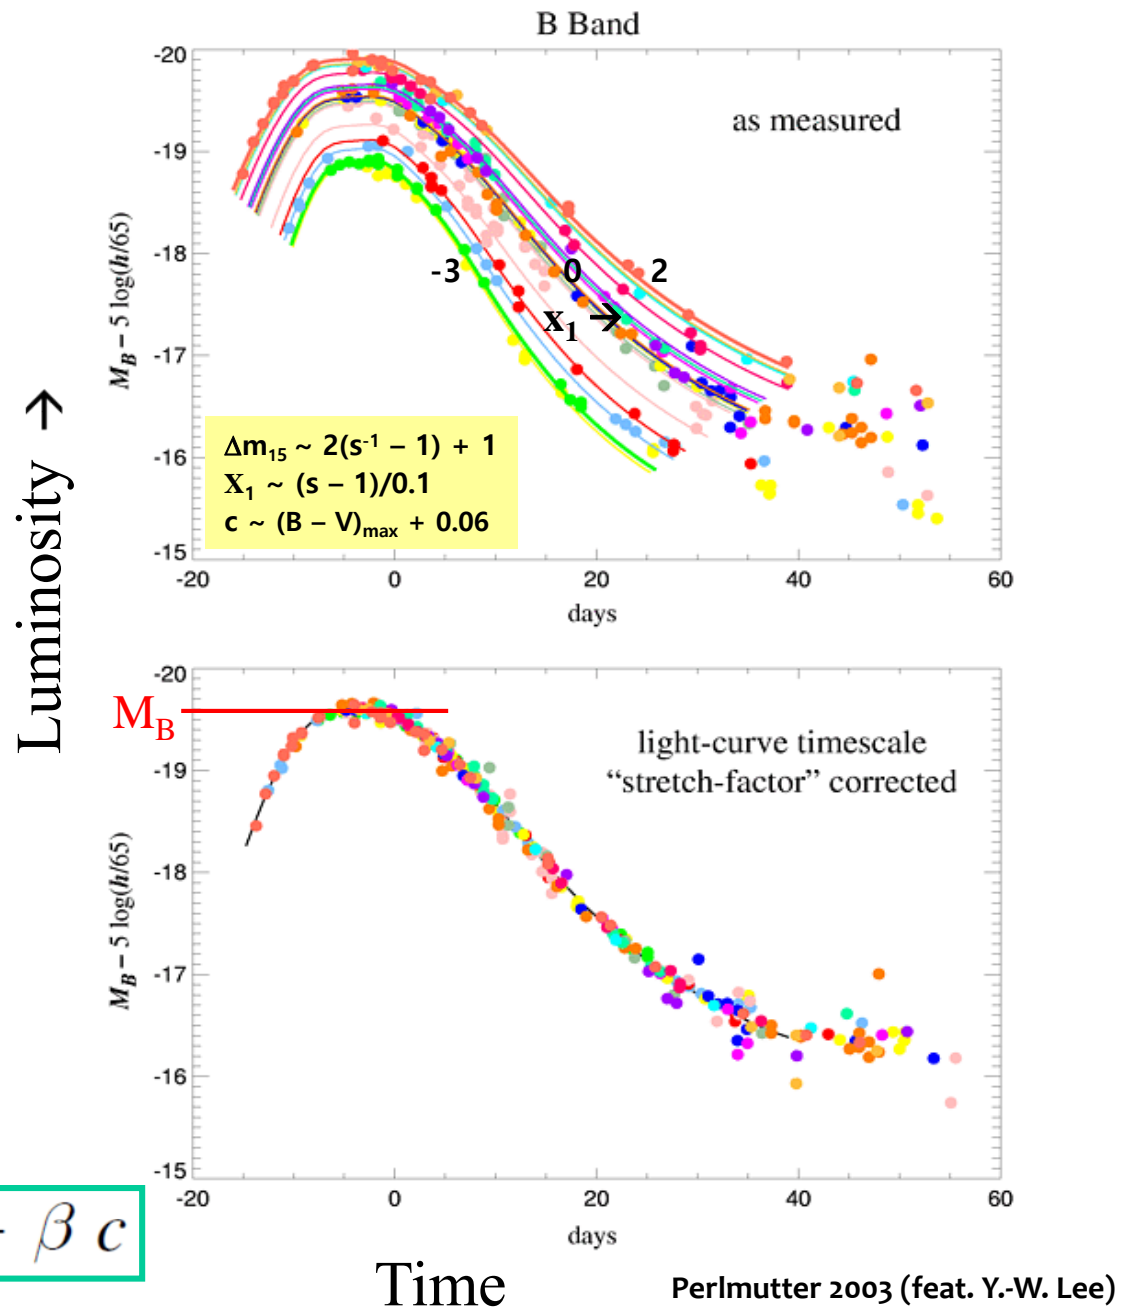

"Standardizable" Candle:

Peak luminosity =
f(light-curve width,
color)

Width/stretch &
color parameters:
 $x_1(s, \Delta m_{15}), c$

Assume no
evolution with z
(progenitor age)

$$\mu = m_B - M + \alpha x_1 - \beta c$$

The Key Assumption & Requirement in Supernova Cosmology

“If SNe Ia are to be good standardisable candles over cosmic time, the calibrating relationships between SN luminosity and light-curve shape must be invariant with progenitor age.”

Jha, Maguire, & Sullivan 2019, Nature Astronomy

$$\mu_B = m_B^* - \mathcal{M}_B + \alpha \times \underset{x_1}{\text{shape}} - \beta \times \underset{c}{\text{color}}$$

\mathcal{M}_B , α and β fitted at the same time as cosmology.

Width – Luminosity relation (WLR)

Color – Luminosity relation (CLR)

Width – Luminosity Relation & Color – Luminosity Relation of Rose+2019 sample ($z \sim 0.14$)

Following Astier, Guy, Sullivan+2006 (previous slide), left panel is corrected only for c , while right panel is corrected only for x_1 to recover WLR & CLR, respectively (x_0 , x_1 , & c from Campbell+13)

Surprising Discovery!! Strong progenitor age dependence of Width – Luminosity Relation & Color – Luminosity Relation

SNe from younger progenitors are fainter each at given x_1 and c

→ Reminiscent of Baade's (1956) discovery of two Cepheid P – L relations !!

→ This 4.6σ result is not sensitive to the choices of (α, β) , young/old split, & SN catalog

(Other host properties show substantially smaller and insignificant offsets) Y.-W. Lee et al. 2022, MNRAS

ABSTRACT

sensitive plates, taken with the 100-inch companions of the Andromeda nebula—Messier 32 and the nebula itself. The brightest stars in all the field have a mean color index $+1.3$ mag. Since the absolute photographic magnitude of the brightest stars is -4.0 mag, the distance modulus is $1.3 - (-4.0) = 5.3$ mag. This leads to a distance of 2.5×10^6 parsecs, or 2.5 million parsecs, or 2.5 million light years.

gram of the stars in the early-type nebulae and the globular clusters. This leads to two distinct groups, one representing the old population (the slow-moving stars), the other (type I) are highly luminous O and B stars, Cepheids and globular clusters of type II. Both types seem to coexist in the same field.

Young population I Cepheids are ~ 1.5 mag brighter than old population II counterparts

→ M31 distance increased by a factor of 2

→ H_0 decreased by a factor of 2!

After standardization, “young” SNe are *over-corrected* & fainter!

$$\mu = m_B - M + \alpha x_1 - \beta c$$

High- z SNe are also from younger population, and, therefore, should be equally over-corrected and become similarly fainter!

Redshift Evolution of Supernova Progenitor Age Distribution

SPAD = Delay Time Distribution (DTD) x Cosmic SFH (Childress+2014; Kang+2020)

Mean population age is getting younger with z: $\Delta t \sim 6$ Gyr ($0 < z < 1$)

When the progenitor age bias (~ 0.035 mag/Gyr) is taken into account, little evidence left for an accelerating universe !!

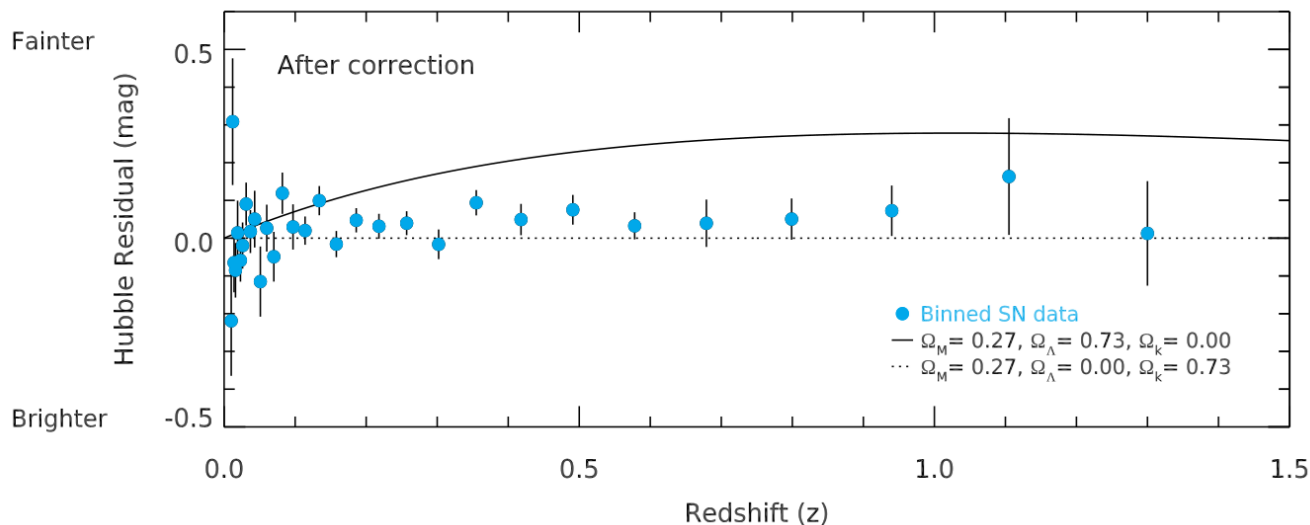

Solid line: Λ CDM model with Ω_Λ (*accelerating*)

Dotted line: The baseline model without Ω_Λ (*non-accelerating*)

Blue circles: Binned SN data (Betoule+14, JLA)

Little evidence left for an accelerating universe !!

The ‘w tension’ in cosmology!

(in the flat-wCDM model)

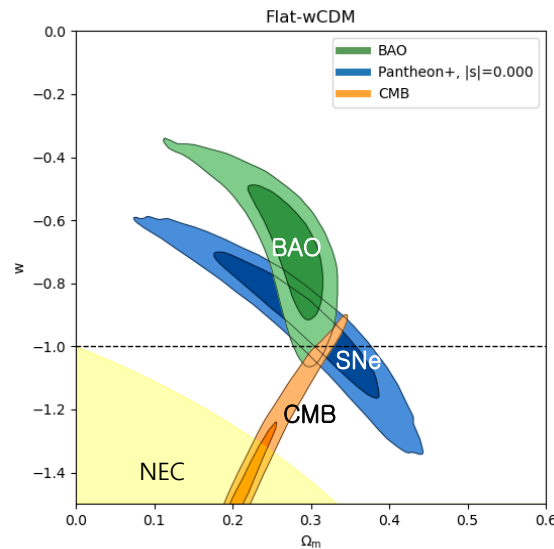

2010
Concordance

(Amanullah+2010)

2023
Discordance

Before Correction

After Correction

After the age-bias correction, a strong ($\sim 6\sigma$) ‘w tension’ between the low- z probes (SNe, BAO) & CMB in the flat-wCDM model, just like the ‘Hubble tension’ between them.

Alcock-Paczynski test also prefers $w > -1$ ($w \sim -0.85 \pm 0.05$; Dong et al. 2023).

Dark energy equation of state parameter $w = P/\rho$ (-1 for ‘Cosmological Constant’, > -1 for ‘Quintessence’)
Data: SNe-only (Brout+2022), BAO-only (Alam+2021), CMB-only (Planck final result 2020)

Summary

- SN cosmology is based on such a fragile assumption which is not supported by our discovery of **strong progenitor age bias in SN luminosity standardization process.**
- When this systematic bias is taken into account, **we have a strong ‘w tension’ between the low-z probes (SNe, BAO) & CMB in the flat-wCDM model.**
- To put this result on a firmer refined basis, follow-up investigations are going on for a larger sample of host galaxies at different redshift bins.
