Massive vs. laminated yokes

Historically, the primary choice was whether the magnet is operated in persistent mode or cycled (**eddy currents**)

- + no stamping, no stacking
- + less expensive for prototypes and small series
- time consuming machining, in particular for complicated pole shapes
- difficult to reach similar magnetic performance between magnets

- + steel sheets less expensive than massive blocks (cast ingot)
- + less expensive for larger series
- + steel properties can be easily tailored
- + uniform magnetic properties over large series
- expensive tooling

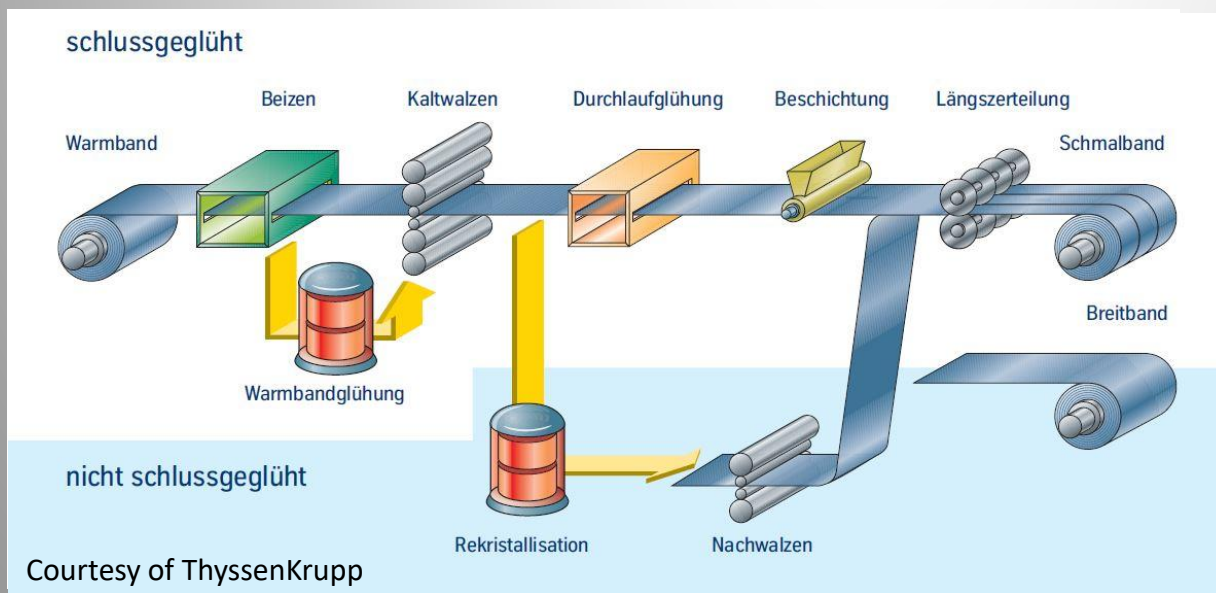

Magnetic steel

Today's standard: cold rolled, non-oriented electro-steel sheets (EN 10106)

- Magnetic and mechanical properties can be adjusted by final annealing
- Reproducible steel quality even over large productions
- Magnetic properties (permeability, coercivity) within small tolerances
- Homogeneity and reproducibility among the magnets of a series can be enhanced by selecting, sorting or shuffling
- Material is usually cheaper, but laminated yokes are labour intensive and require more expensive tooling (fine blanking, stacking)

NGO steel properties

ISOVAC 1300-100A: $H_c = 65$ A/m

ISOVAC 250-35HP: $H_c = 30$ A/m

Sheet thickness: $0.3 \leq t \leq 1.5$ mm

Specific weight: $7.60 \leq \delta \leq 7.85$ g/cm³

Electr. resistivity @20°C:

0.16 (low Si) $\leq \rho \leq 0.61$ $\mu\Omega\text{m}$ (high Si)

Sheet insulation

Surface coating:

- electrical insulation of several μm thickness
- one or both sides
- oxid layer, phosphate layer, organic or inorganic coating

Insulation designation IEC 60404-1-1	Insulation type	Color ¹⁾	Coating	Coating thickness each side in μm	Insulation resistance at room temperature to ASTM A717/A717M-95 $\Omega\text{m}^2/\text{Lamelle}$
STABOLIT 10 EC-3 by prior arrangement only	organic	yellow-green	both sides	max. 1.5	> 15
STABOLIT 20 EC-5-P	inorganic with organic components	grey-green	both sides	0.5 – 1.5	> 5
STABOLIT 30 EC-5-P	inorganic with organic components	light grey	both sides	0.5 - 1.5	> 5
STABOLIT 40 EC-6	organic pigmented	grey	one or both sides	3.0 - 5.0 4.0 - 7.0 6.0 - 9.0	> 90
STABOLIT 60 EC-5	inorganic with organic components pigmented	grey	both sides	0.3 - 1.0 1.0 - 2.0 2.0 - 3.5	> 5 > 15 > 50
STABOLIT 70	organic bonding lacquer (active)	colorless	one or both sides	5.0 - 8.0	-
Combined insulation	organic bonding lacquer with one side heat treatment (passive)	colorless	both sides	active 5.0 - 8.0 passive max. 1.5	-

Sample testing

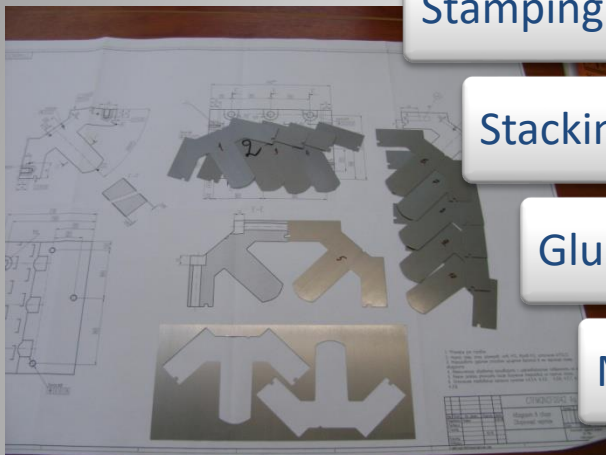

Samples are tested to validate material properties:

Yoke manufacturing

Stamping laminations

Stacking laminations into yokes

Gluing and/or welding

Machining

Assembly (preliminary)

Lamination punching

- Punching or fine blanking
- Fine blanking requires more expensive tooling
- Tolerances less than +/- 8 μm achievable (depending on thickness, material and layout)
- Material can be delivered in sheets or strips (coils)

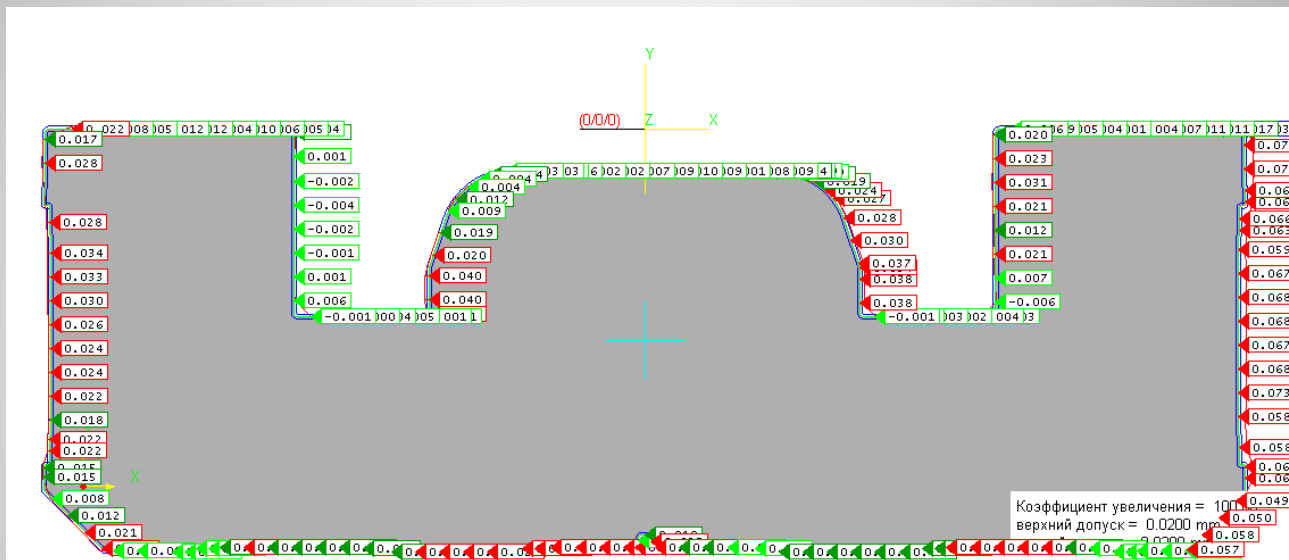

Sample testing

Samples are tested to validate the lamination contour:

Yoke stacking

Fixtures for stacking/baking/welding

Glueing vs. Welding

Welding

- + mechanically more rigid
- + no aging
- massive end plates/tension straps needed
- continuous welding introduces stress and deformation
- sophisticated welding procedure
- / requires stacking fixture

Glueing

- + no stress, no distortions
- + no tension straps, no end plates
(→ no eddy currents)
- glue sensitive to radiation and aging
- requires clean laminations and conditions
- requires baking oven
- / requires stacking fixture

Recommendation: combine glueing, welding & bolting

Recurrent quality issues

Poor lamination bonding strength

Coil manufacturing

Define conductor type and material

Conductor insulation

Winding

Ground insulation

Epoxy impregnation

Conductor materials

	Al	Cu (OF)
Purity	99.7 %	99.95 %
Resistivity @ 20°C	2.83 μΩ cm	1.72 μΩ cm
Thermal resistivity coeff.	0.004 K ⁻¹	0.004 K ⁻¹
Specific weight	2.70 g/cm ³	8.94 g/cm ³
Thermal conductivity	2.37 W/cm K	3.91 W/cm K

Key-stoning: risk of insulation damage & decrease of cooling duct cross-section

$$R = 3 \cdot A \Rightarrow \frac{\Delta A}{A} = 3.6\%$$

Coil insulation

In a magnet coil, the electrical insulation ensures that current flows only along the conductors and not between individual conductors or between the conductors and other parts of the magnet

Dielectric materials can be distinguished in three main classes:

- inorganic materials: ceramics, glass, quartz, cements and minerals (e.g. mica)
- organic materials: thermoplastic: Rubber, PA (Nylon), PP, PS, PVC, PC, PTFE or thermosetting: Polyethylene, PI, PEEK, Epoxy, phenolic, silicon, polyester resins
- composites: fully organic (aramidic fibres-epoxy tapes) or mixed (epoxy-mica tapes)

A weak electrical insulation may produce:

- current leaks with local heating up to melting and possible fire
- progressive damage of the leakage path up to a short circuit
- unbalanced circulating currents (→ magnetic field distortion)
- incorrect functioning of protections

The electrical insulation is stressed by several factors:

- electric
- thermal
- mechanical
- chemical (including oxidation)
- radiation

Montsinger's rule / Arrhenius equation: $L(T + 10 K) \approx 0.5 t(T)$

A temperature rise of 10 K halves the expected live time of an insulation system

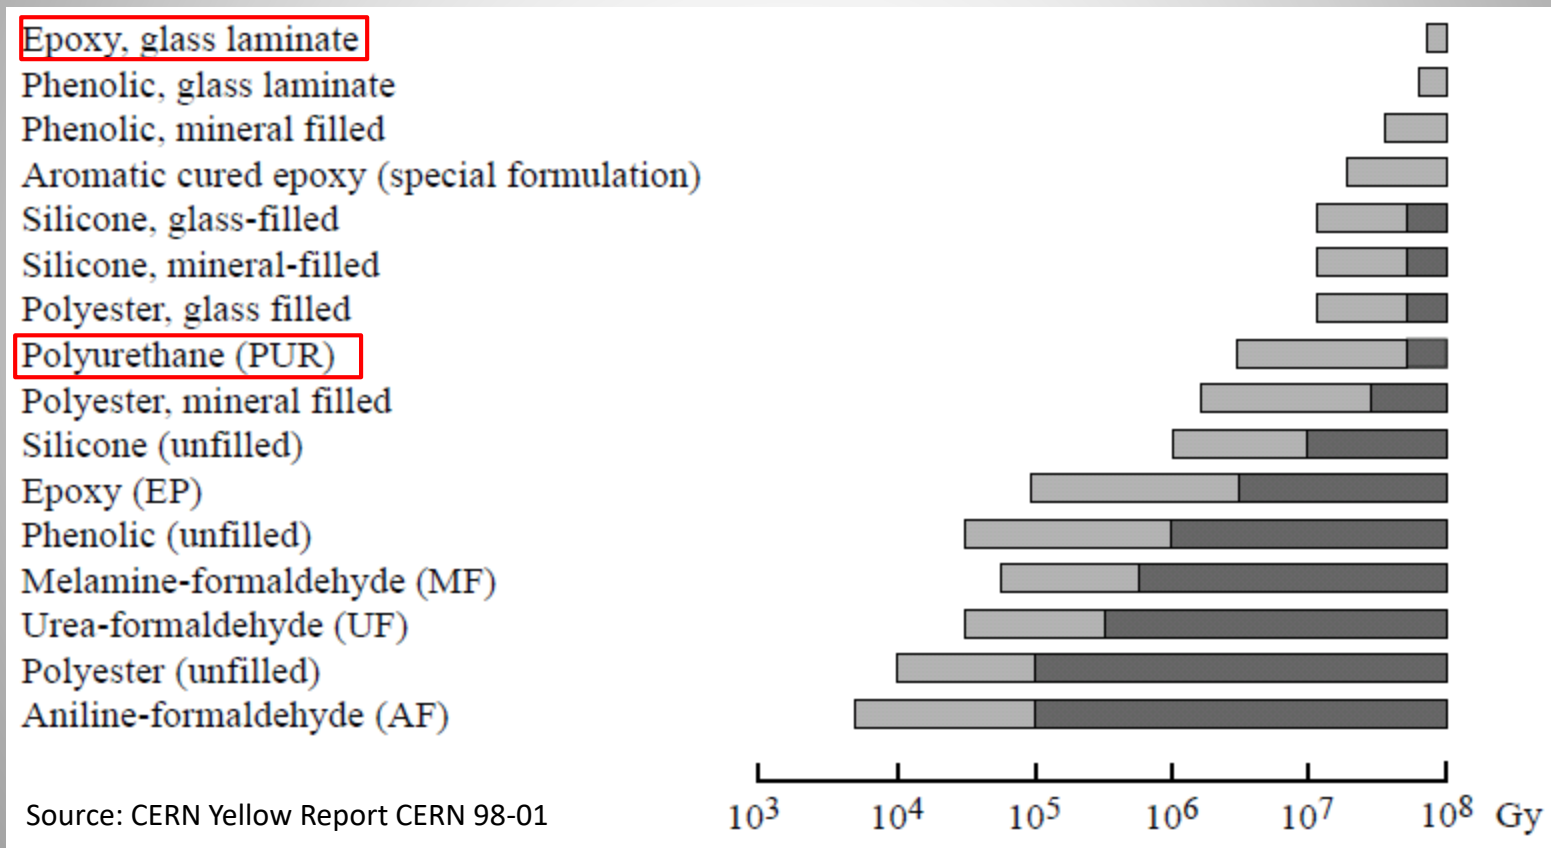

Reference: D. Tommasini: Dielectric insulation and high-voltage issues, CAS 2009, Brugges

Radiation hardness

Radiation hardness is an important criterion for insulation materials used for accelerator applications

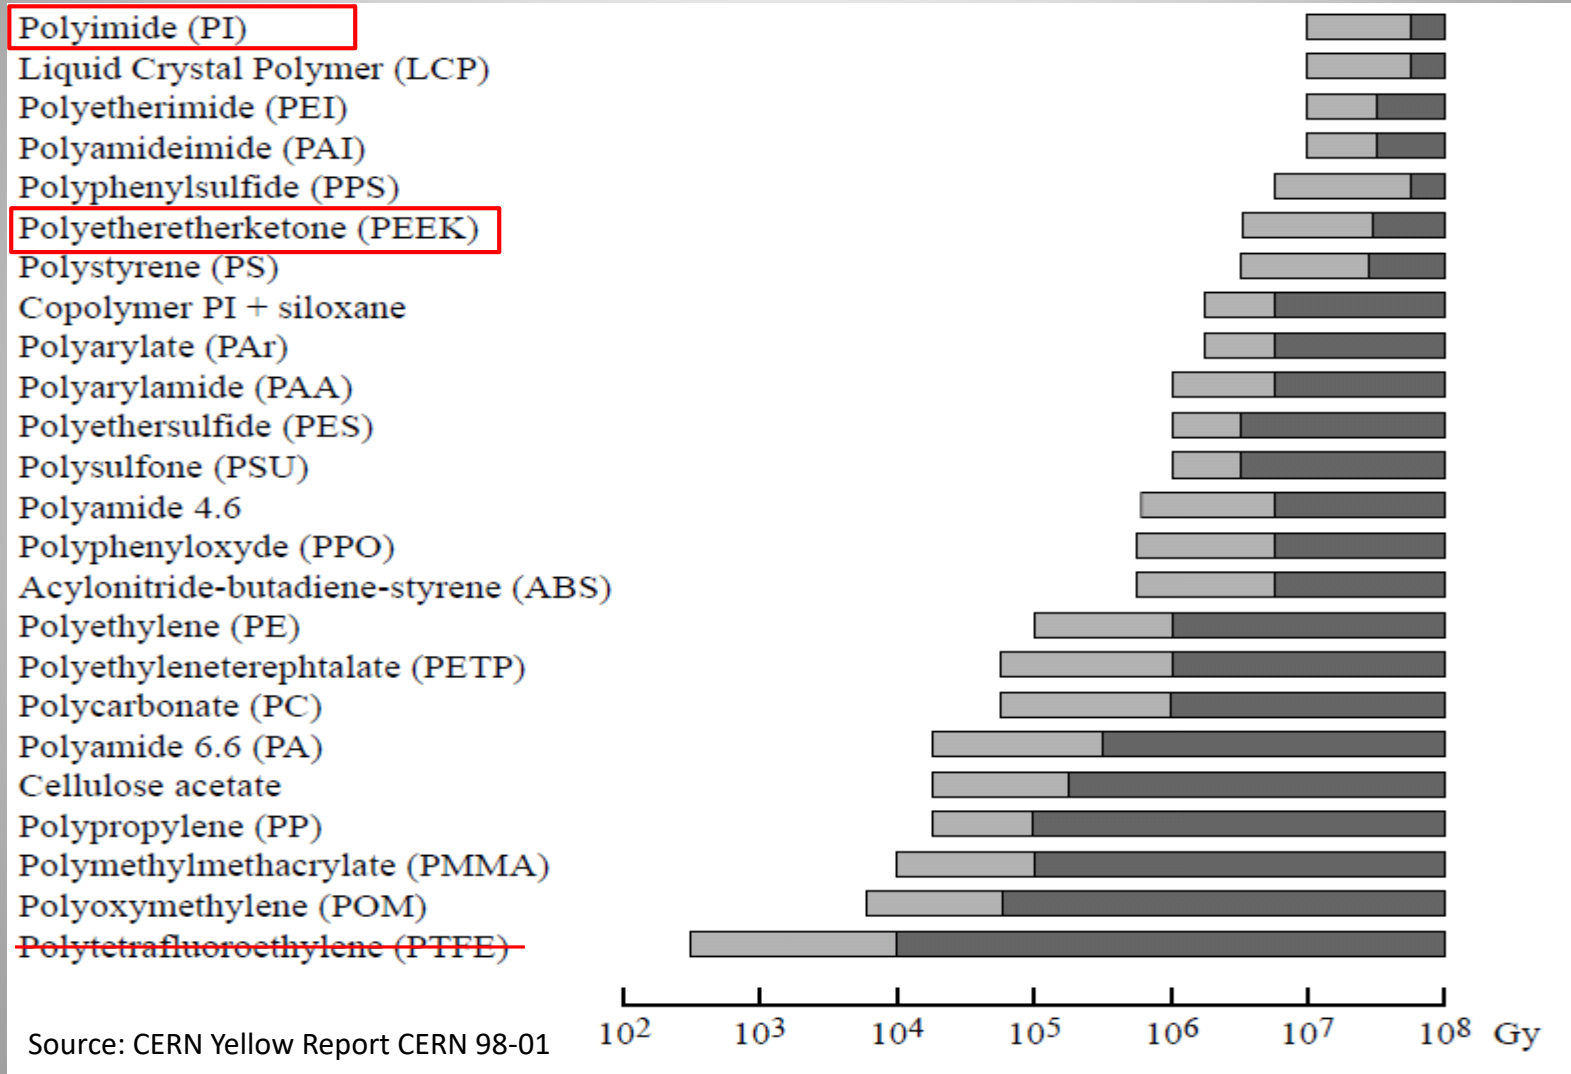

Above 10⁸ Gy special insulation techniques are required!

Radiation hardness

Coil insulation

Conductors with small cross-section:

straighthening → cleaning → conductor insulation → winding → ground insulation

Coil impregnation

heating and evacuating mold and coil (auto-clave or vacuum mold) → mixing resing → heating and degassing resin → injecting resin → curing cycle → cooling

Recurrent quality issues

Lack of resin: bubbles, voids, fissures, cracks, poor penetration, poor wetting
Electrical HV and discharge insulation test shall reveal 'hidden' defects

Magnet assembly

By hand....

... or with the help of tooling

Auxiliary components

- Electrical connections
- Hydraulic connections
- Interlock system (temperature, pressure, water flow)
- Alignment targets, adjustment tables and support jacks
- Magnetic measurement devices (pick-up coils, hall probes)

Hydraulic circuits

- Water circuits are most critical items
- 95% of all magnet failures due to water leaks:
 - Corrosion
 - Erosion
 - Poor brazing quality
 - Poor welding quality
 - Failure or aging of joints
 - Inadequate materials
 - Incorrect assembly
 - Radiation damage
 - Inadequate design

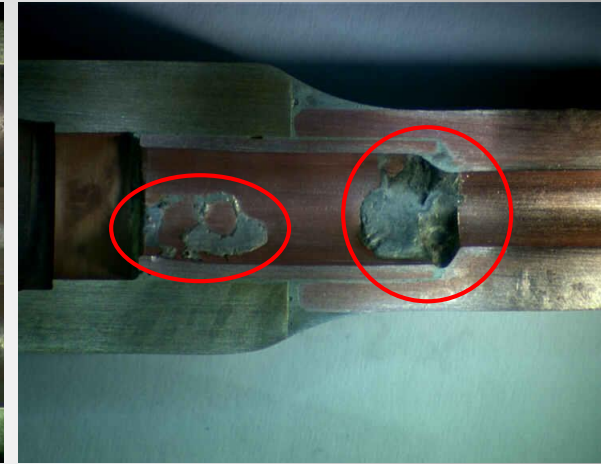

- Leaks can be detected and repaired during magnet acceptance tests and commissioning...
- ... but, many leaks occur only after years in operation
- Often not monitored → magnet damage (short circuits, corrosion of iron yoke) and collateral damages on other equipment

Recurrent quality issues

Lack/excess of brazing filler

Interlock Sensors

Thermo-switch:

Flow-switch:

QA & Acceptance tests

QA is important at **each** production stage:

- Constant monitoring of critical items from the raw material, to semi-finished parts, to sub-components to the final product
- Sample testing (destructive or non-destructive) to qualify materials, manufacturing techniques and processes
- Acceptance tests can include electrical, hydraulic, mechanical, thermal, and magnetic measurements
- Tests/measurements can be systematically (entire series) or on specific/random samples

More details: see practical work @ CERN

Magnetic measurements

Magnetic measurements are performed to:

- characterize soft (iron) and hard (permanent magnets) ferromagnetic materials
- prove that the electro-magnetic design is correct
- monitor production quality and steer manufacturing
- collect information and data for operation: polarity, transfer function, field uniformity, magnetic axis, dynamic effects (eddy currents) and magnetic cycling effects (hysteresis)
- characterize magnets after repairs or to use in different operational ranges

More details: see practical work @ CERN

Summary

- Magnet design has a direct impact on manufacturing (and vice versa)
- The yoke shape and dimensional accuracy is essential for magnetic field quality in iron-dominated magnets
- The manufacturing techniques shall be adapted to meet the specified requirements of the final product in all respects
- **Tight QA** is the key for success and important at each production stage
 - Sample testing to qualify materials, manufacturing techniques and processes
 - Acceptance tests to verify the correct performance of the final product
 - Magnetic measurements are an essential part of the qualification process
