

## Strong first order phase transition in composite Higgs models

*Thursday, 5 December 2019 16:30 (30 minutes)*

We study the strong first order electroweak phase transition (SFOEWPT) with the  $SO(6)/SO(5)$  composite Higgs model, whose scalar sector contains one Higgs doublet and one real singlet. Six benchmark models are built with fermion embeddings in 1, 6, and 15 of  $SO(6)$ . We show that SFOEWPT cannot be triggered under the minimal Higgs potential hypothesis, which assumes the scalar potential is dominated by the form factors from the lightest composite resonances. To get a SFOEWPT, the contributions from local operators induced by physics above the cutoff scale are needed. We take the  $6 + 6$  model as an example to investigate the gravitational waves prediction and the related collider phenomenology.
