

Probing nucleon's structure using Drell-Yan process with unpolarized/polarized targets at Fermilab

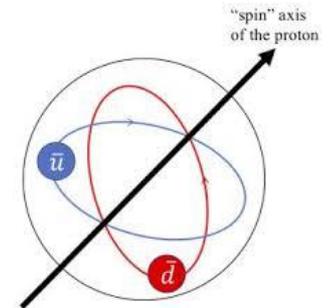

Andrew Chen

University of Illinois, Urbana Champaign, USA

For the E906/E1039 collaboration at Fermilab

CPHI 2020, CERN

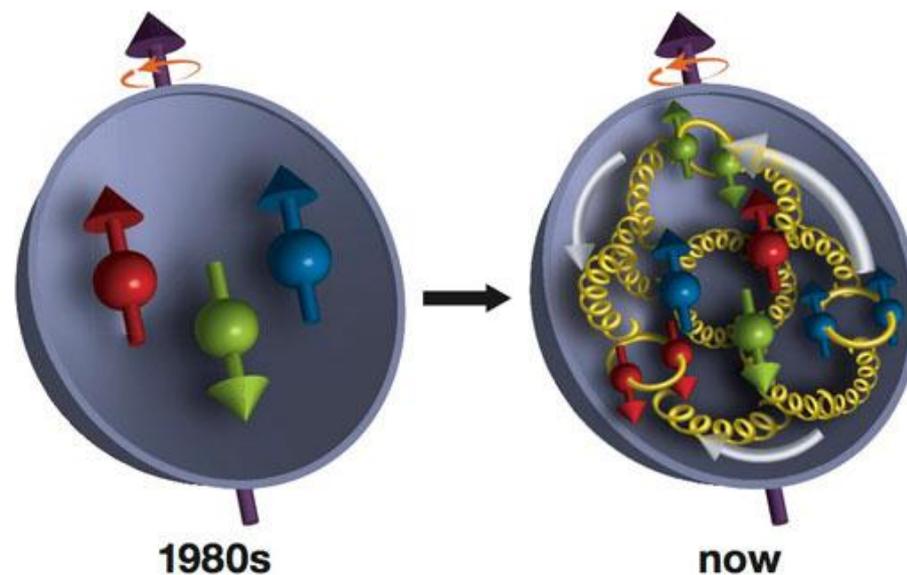

Outline

- Introduction
- Physics goals
 - The **SeaQuest** experiment
 - \bar{d}/\bar{u} asymmetry
 - The **SpinQuest** experiment
 - Probing sea-quarks
 - Sivers function, transversity
 - Tensor Charge
 - Tensor polarization

Introduction

- Proton has been discovered a century ago and yet its structure is not fully understood.

- \bar{d}/\bar{u} asymmetry -> [SeaQuest/E906](#)
- The sea-quark Orbital Angular Momentum, O.A.M. could lead to non-zero single-spin asymmetry -> [SpinQuest/E1039](#)

The \bar{d}/\bar{u} asymmetry

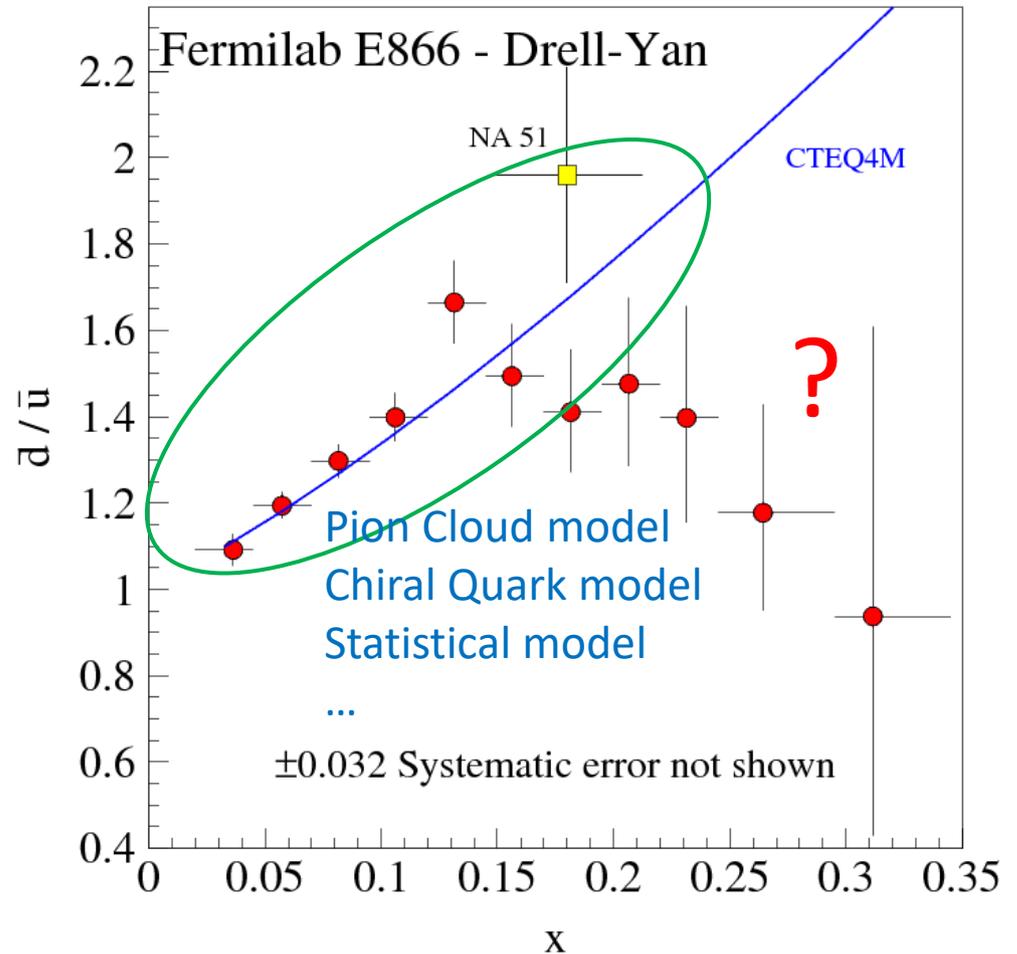

- The Gottfried sum

$$S_G = \frac{1}{3} - \frac{2}{3} \int_0^1 [\bar{d}^p(x) - \bar{u}^p] dx$$

- NMC observes

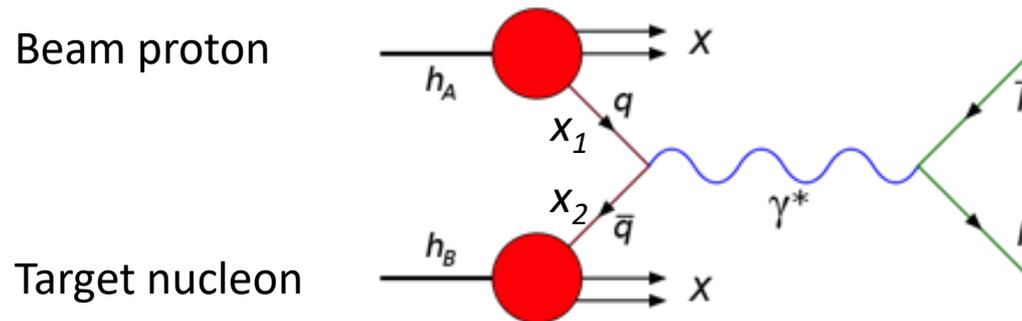

$$\int_0^1 [\bar{d}^p(x) - \bar{u}^p(x)] dx = 0.148 \pm 0.039$$

- E866 shows that the asymmetry has strong dependence on Bjorken x !
- Although with large uncertainty, the dropping in high x is hard to explain.

The SeaQuest experiment

- The Drell-Yan process:

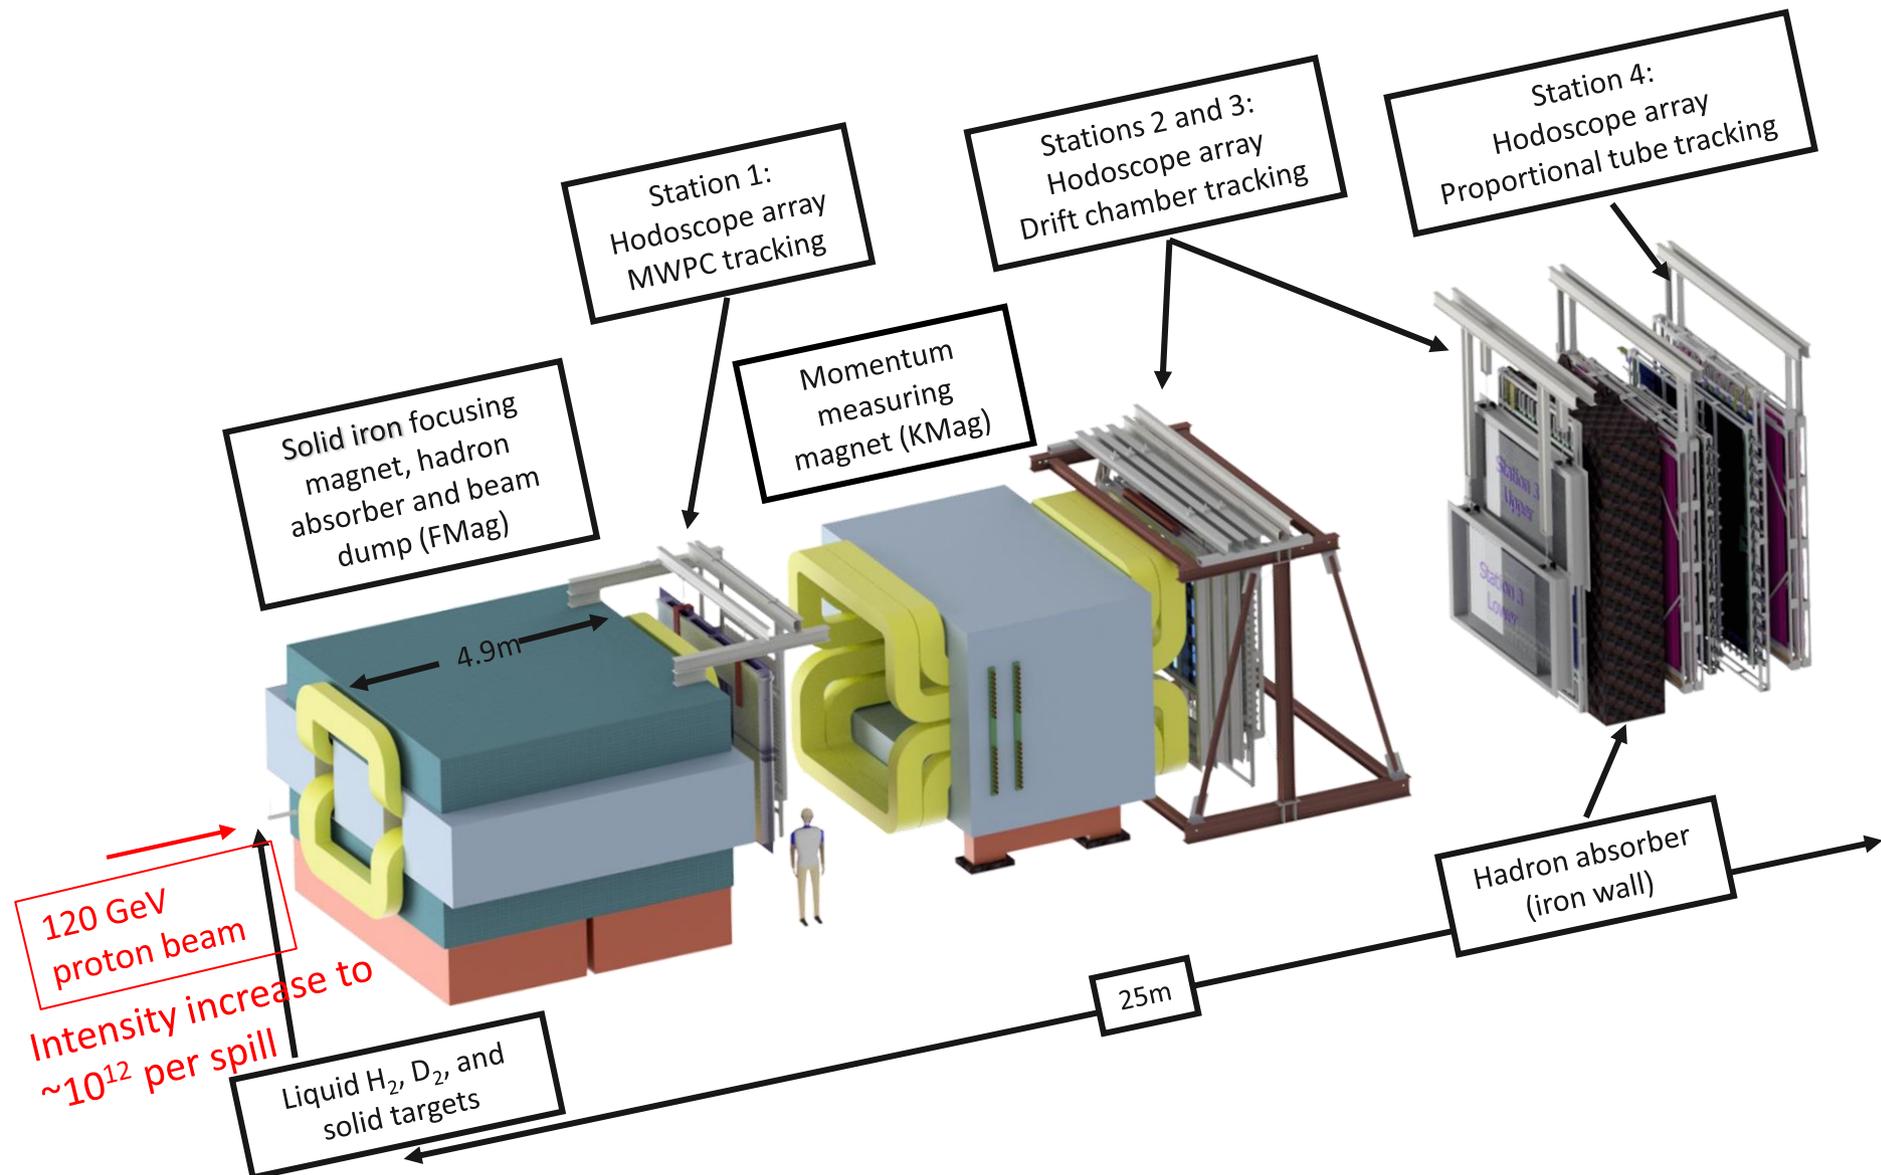

- Due to the acceptance the experiment probes mainly **anti-quarks** in the target nucleon.

$$\frac{d^2\sigma}{dx_1 dx_2} \Big|_{DY} = \frac{4\pi\alpha^2}{9sx_1 x_2} \sum_q e_q^2 [f^q(x_1) \cdot f^{\bar{q}}(x_2) + \cancel{f^{\bar{q}}(x_1) \cdot f^q(x_2)}]$$

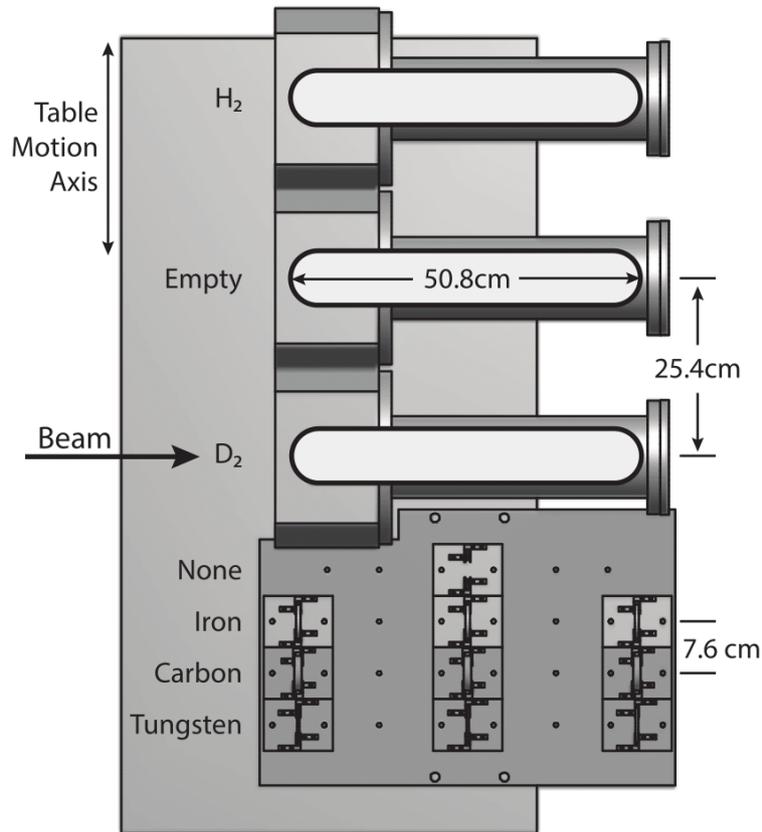

- To increase statistics, the beam energy is reduced to 120 GeV.

- From cross-section ratio to \bar{d}/\bar{u} : $\frac{\sigma^{pd}(x)}{2\sigma^{pp}(x)} \simeq \frac{1}{2} \left(1 + \frac{\bar{d}(x)}{\bar{u}(x)} \right)$

The SeaQuest spectrometer

The targets

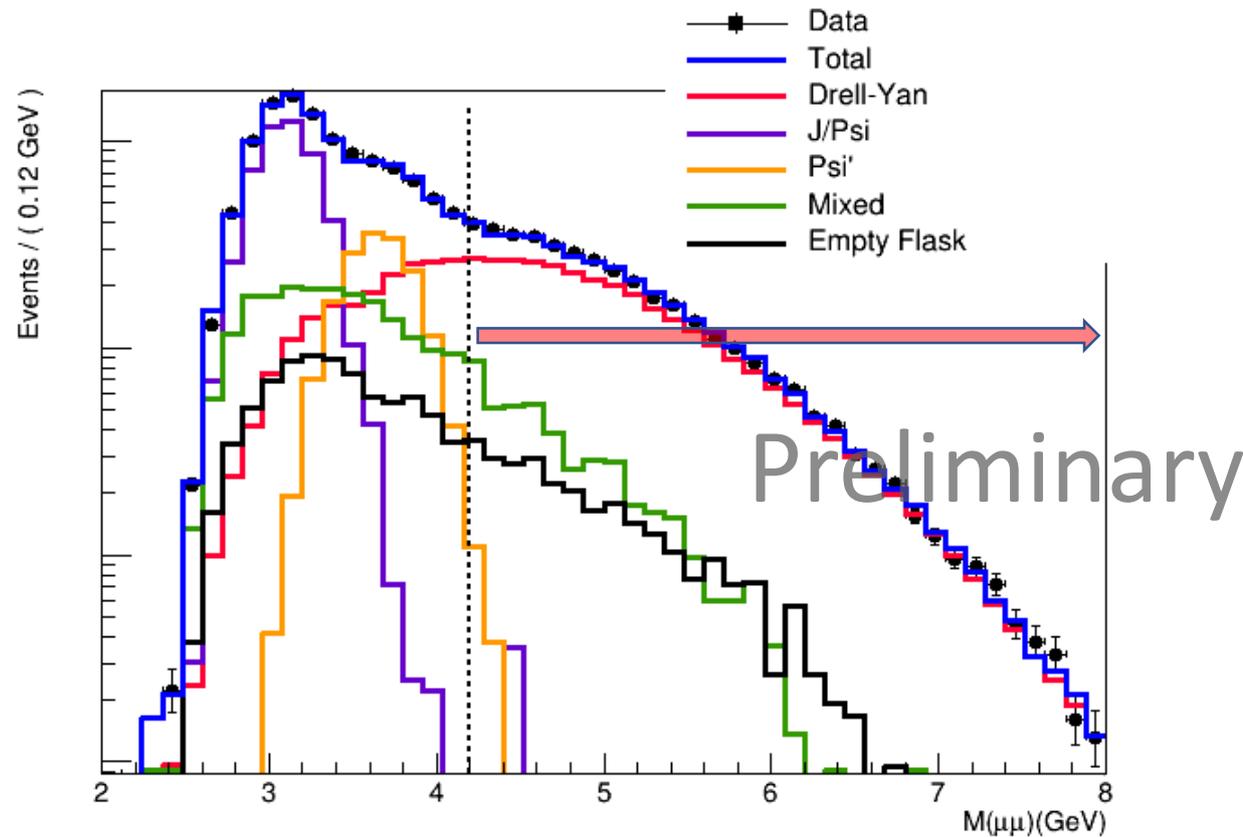

- Changing target, spill by spill.
- Twice as many spills are given to LH2 than LD2.
- Empty flask provides important background events.

The SeaQuest data

- The SeaQuest experiment completed taking data in 2017.
- Preliminary result based on 50% of data.

Dimuon mass distribution

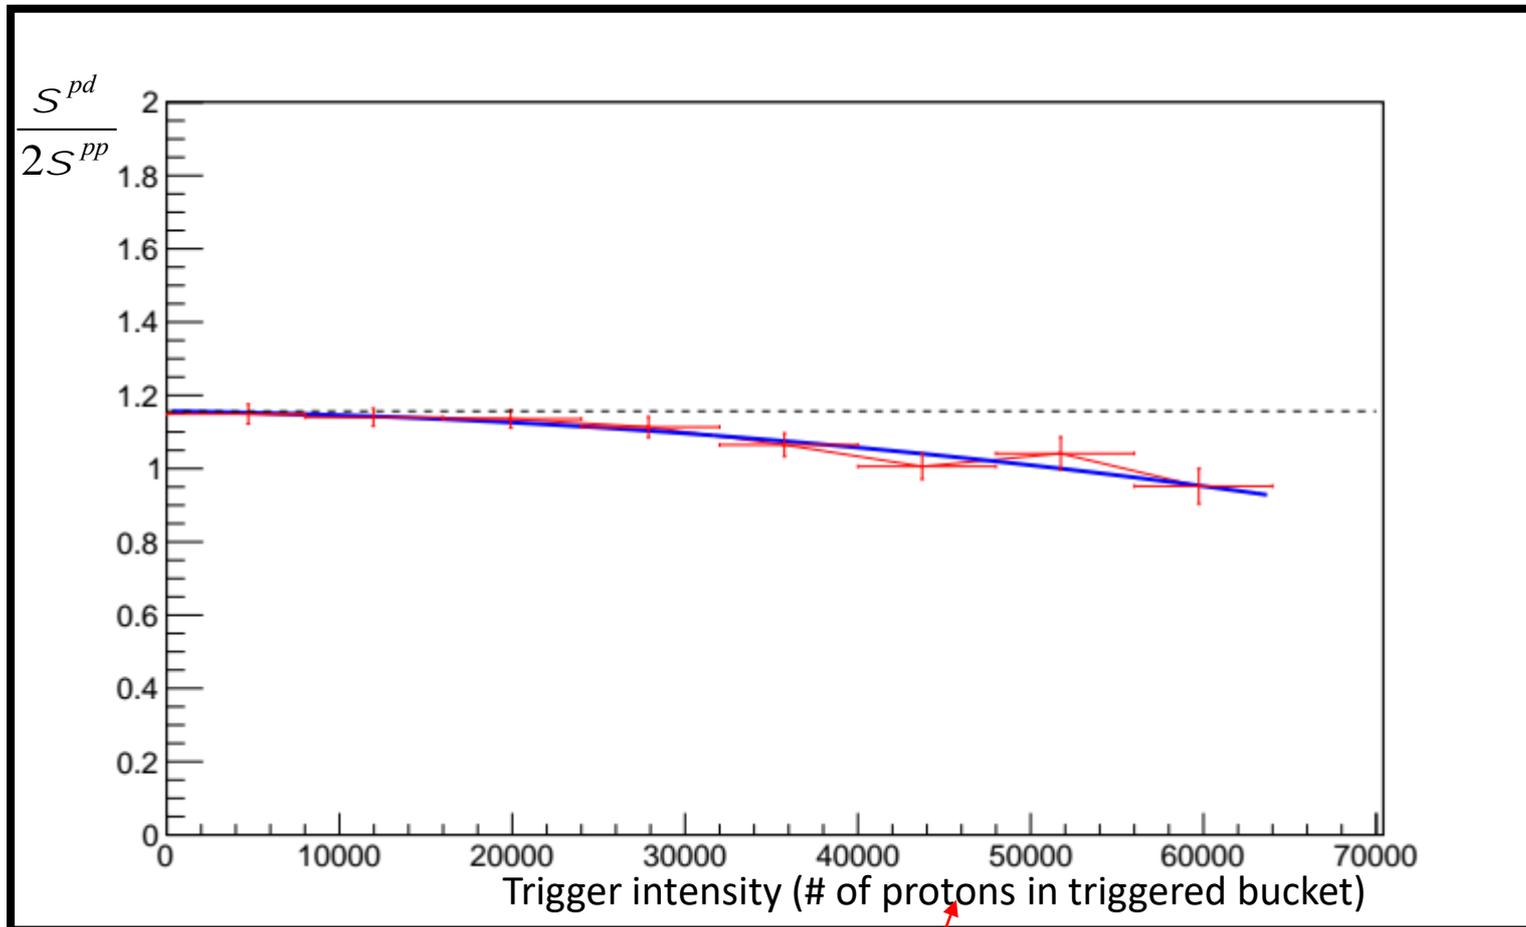

- Reducing of the beam energy with higher intensity, this produces huge background confusing the events from targets.
- “Mixed” background are combinatorial events with tracks from target and FMag after all event selection criteria.

The background and rate dependence

- Extrapolation method based on **cross-section ratio** dependence on **proton intensity** is used.
 - This dependence comes from **background** and the **rate dependence** of the analysis.
 - Find the dependence of the **cross-section ratio** on the **intensity**;
 - **fits the distribution** with function and **project back to zero intensity** to get an answer.
 - Difference between the answers obtained using different functions is taken as part of systemic uncertainty.

$$f_i(I_p) = P0_i + (P10 + P11 \cdot x_2)I_p + (P20 + P21 \cdot x_2)I_p^2$$

Cross-section ratio dependence on x_2

Proton spin, large sea quark O.A.M. contribution?

- Proton spin:

$$\frac{1}{2} = \frac{1}{2} \Delta\Sigma + \Delta G + L$$

$$\Delta\Sigma = \Delta u + \Delta d + \Delta s$$

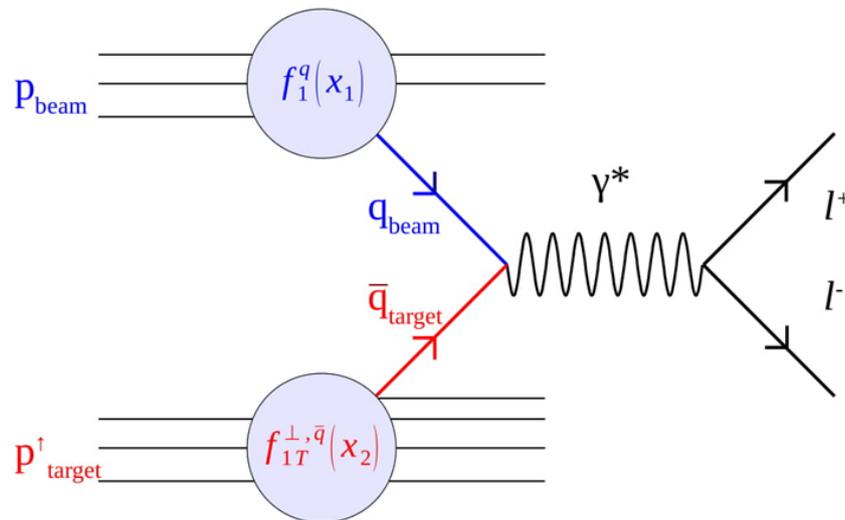

$$\frac{1}{2} \Delta\Sigma \approx 25\% \quad \Delta G \approx 0 - 15\%$$

- Contribution of **quark OAM** is poorly known.
- Contribution of **sea quark OAM** is not measured!
 - Lattice calculation indicates that this might contribute as much as **50%**!
 - Sea quark OAM could lead to non-zero Sivers function of sea quark thus single-spin asymmetry. This leads to SpinQuest experiment at Fermilab.

Sea Quark Sivers function in SpinQuest

- Quark Sivers TMD directly accessible using Polarized SIDIS, **Polarized Drell-Yan**

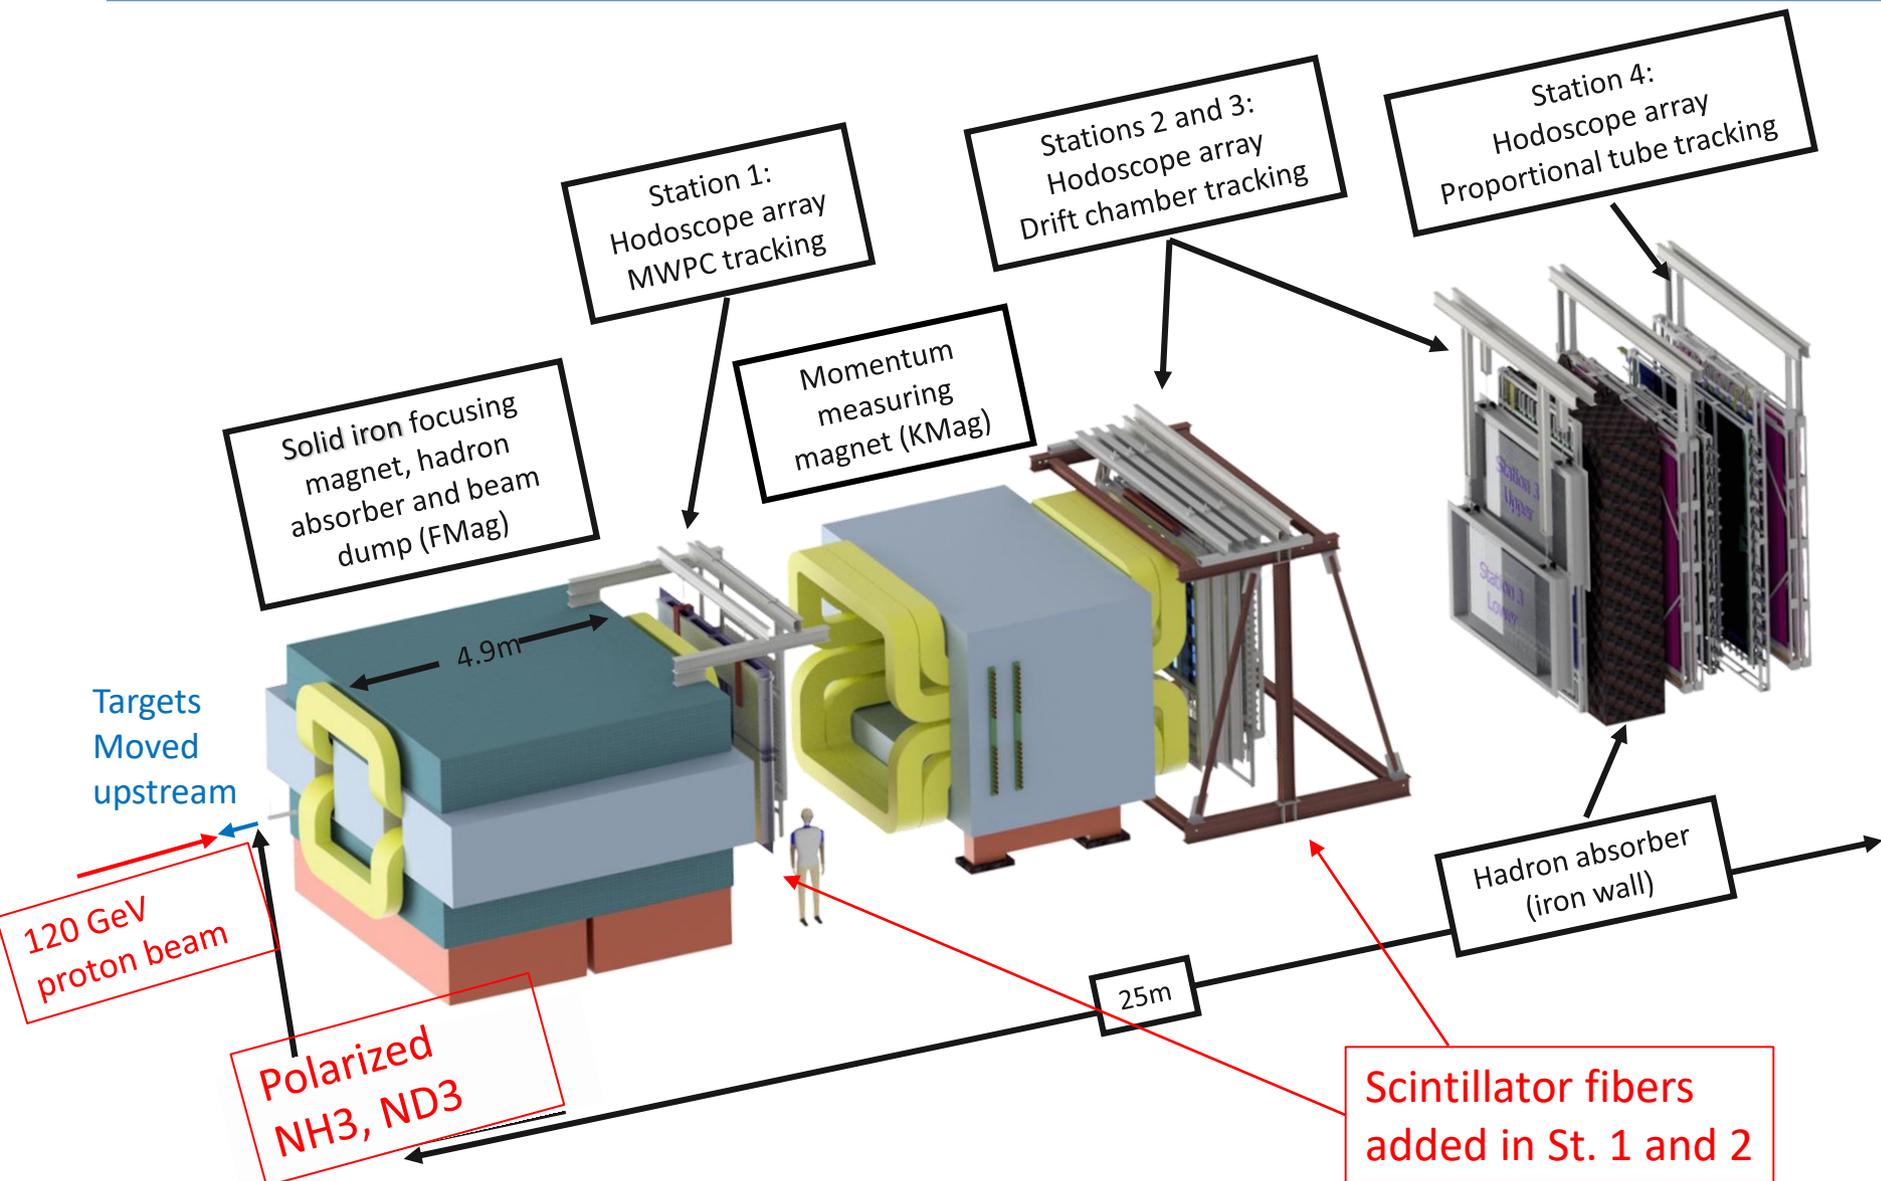

Polarized Drell-Yan

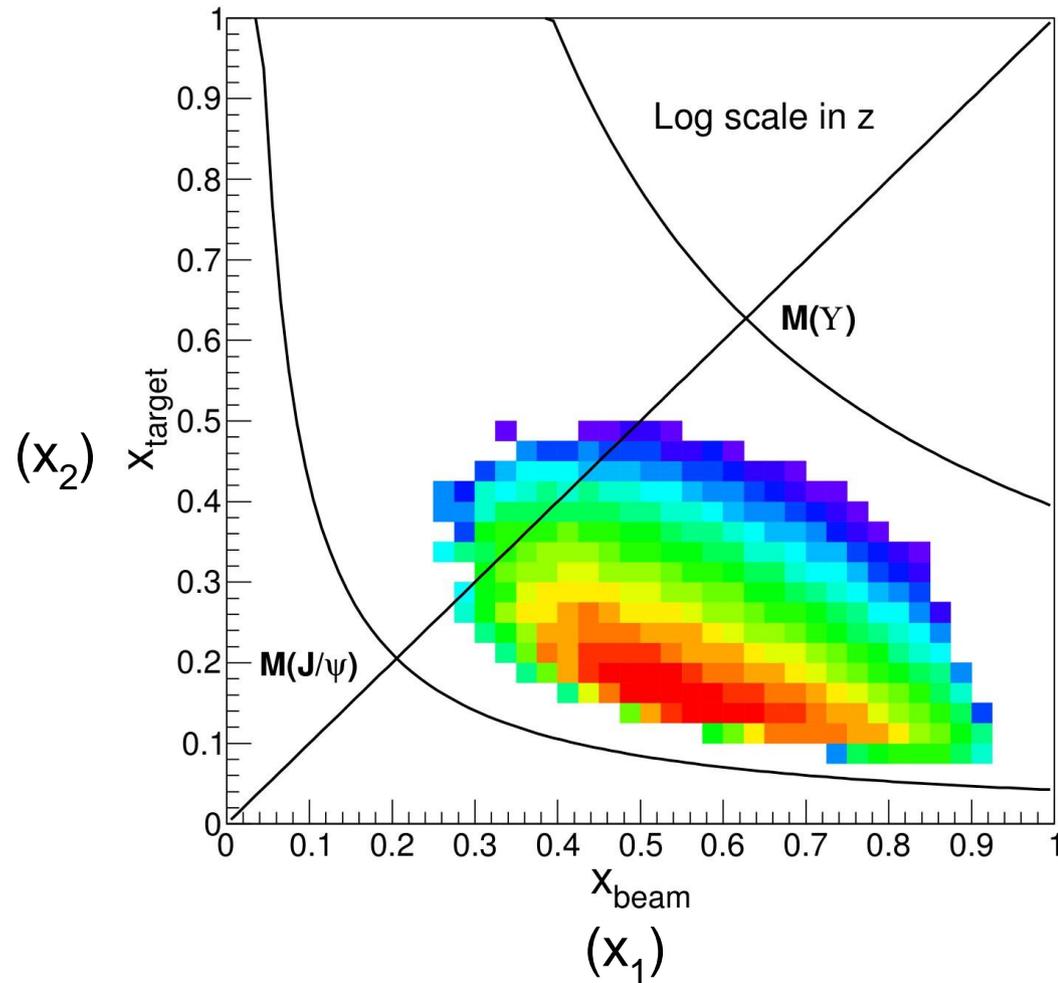

$$A_N^{DY} \propto \frac{\sum_q e_q^2 [f_1^q(x_1) \cdot f_{1T}^{\perp, \bar{q}}(x_2) + 1 \leftrightarrow 2]}{\sum_q e_q^2 [f_1^q(x_1) \cdot f_1^{\bar{q}}(x_2) + 1 \leftrightarrow 2]}$$

- L-R single spin asymmetry in Drell-Yan production
- No Quark Fragmentation function**
- Valence-Sea quark **Isolated.**
- A fixed target Drell-Yan Experiment with polarized target isolates sea quark Sivers TMD to target!**

Transversity

- Transversity describes the correlation between (sea) quark's transverse spin and the nucleon's transverse spin.

$$\frac{d\sigma}{dq^4 d\Omega} \propto \hat{\sigma}_U \left\{ 1 + S_T \left[D_1 A_T^{\sin \varphi_S} \sin \varphi_S + D_2 \left(A_T^{\sin(2\varphi_{CS} - \varphi_S)} \sin(2\varphi_{CS} - \varphi_S) + A_T^{\sin(2\varphi_{CS} + \varphi_S)} \sin(2\varphi_{CS} + \varphi_S) \right) \right] \right\}$$

Transversity convoluted with B-M function

Result of COMPASS, DY (2015)

Tensor Charge

$$\delta q = \int_0^1 [h_1^q(x) - h_1^{\bar{q}}(x)] dx$$

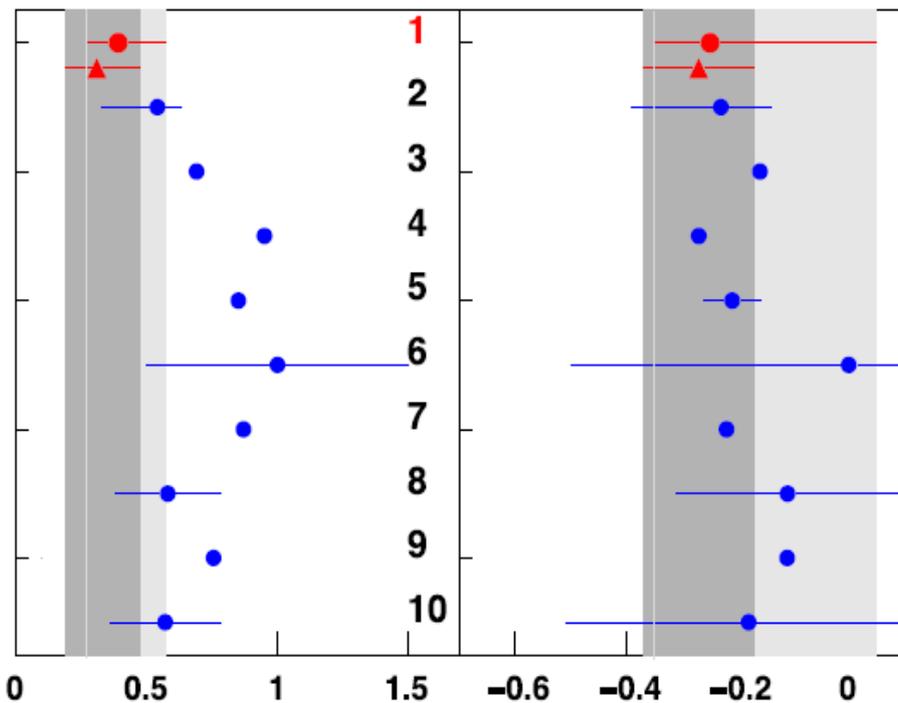

Where h_1 is the transversity of given quark.

● $\delta u = 0.39^{+0.18}_{-0.12}$

● $\delta d = -0.25^{+0.30}_{-0.10}$

▲ $\delta u = 0.31^{+0.16}_{-0.12}$

▲ $\delta d = -0.27^{+0.10}_{-0.10}$

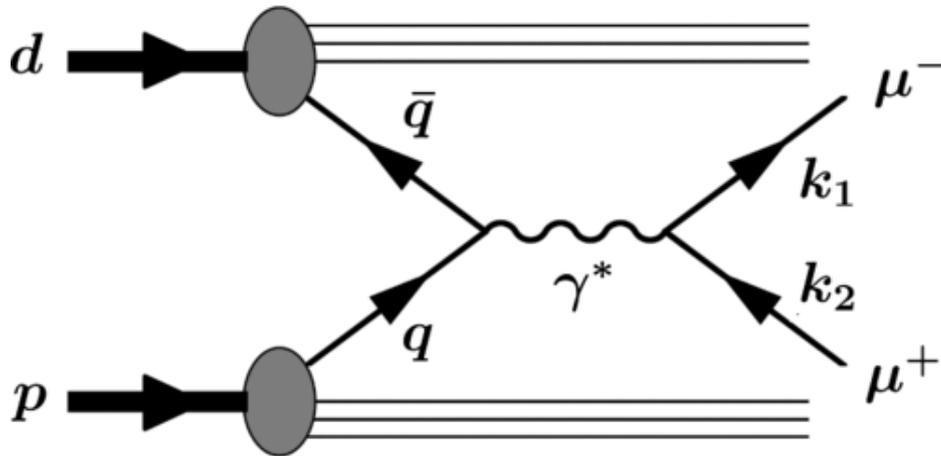

- Global fit with two different Collins Fragmentation Functions.
- This fit neglects the contributions from sea quarks also with limited x range.

Predictions from various models.

E1039, polarized DY, can provide transversity without Fragmentation Functions!

Tensor Polarization

- Tensor polarization in Drell-Yan process of

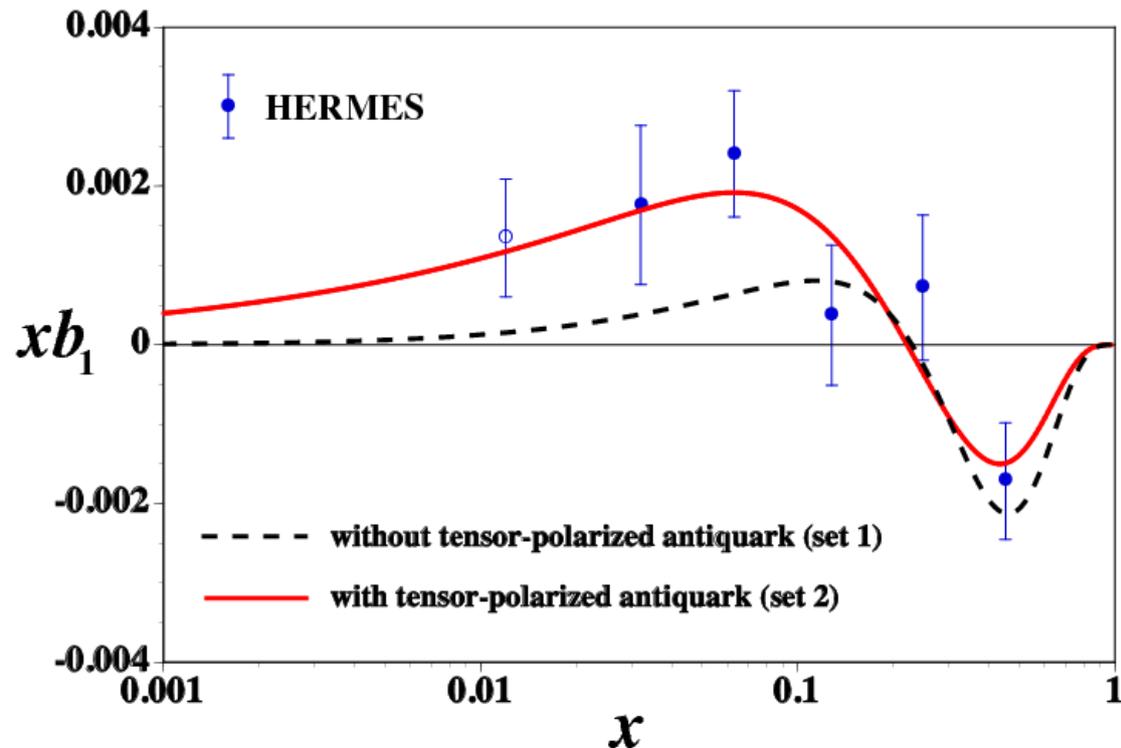

$$p + d \rightarrow \mu^+ + \mu^-$$

where deuteron, d , is **polarized**.

- Deuteron is spin 1, has three magnetic substates:
 - $m = +1, 0, -1$
- Tensor polarization terms leads to new PDFs, b_1, b_2, b_3 and b_4 .
- Where b_1 express the difference between $|m| = 1$ and $|m| = 0$.

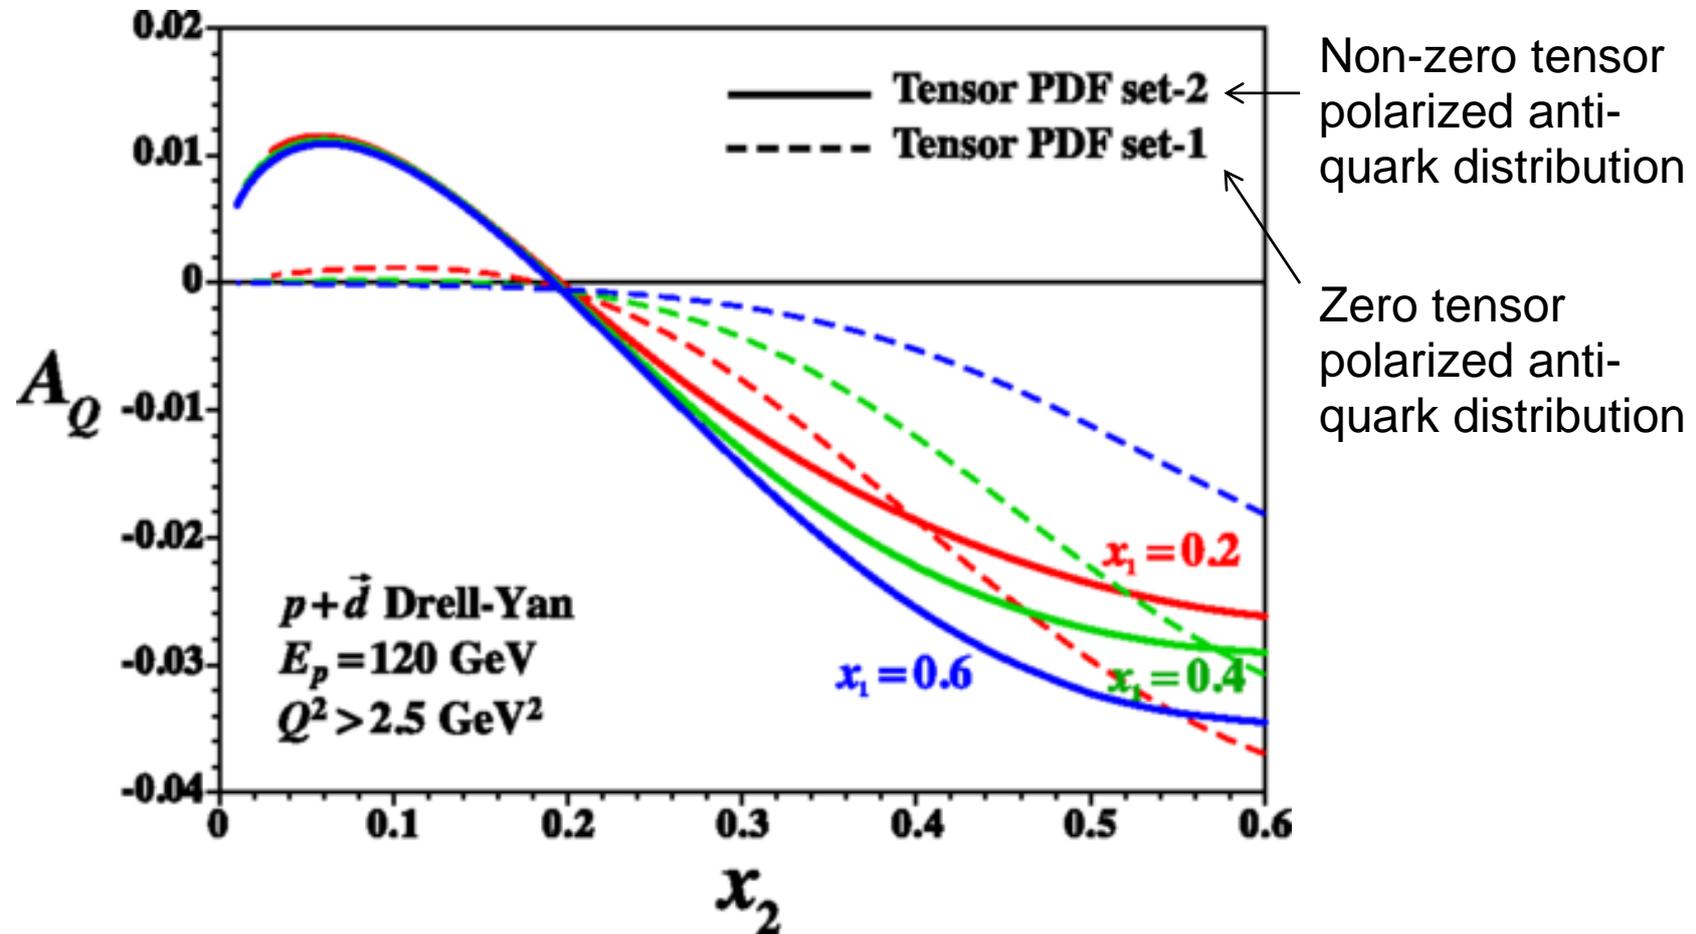

Tensor polarization of antiquark

- Fitting HERMES data with
 - zero tensor-polarized antiquark distributions (set 1)
 - non-zero tensor-polarized antiquark distributions (set 2).
- The HERMES data supports better the case of non-zero tensor polarization PDFs of antiquarks.

S. Kumano and Qin-Tao Song, PhysRev.D 94, 054022

Tensor asymmetry with polarized deuteron, for E1039, predicted

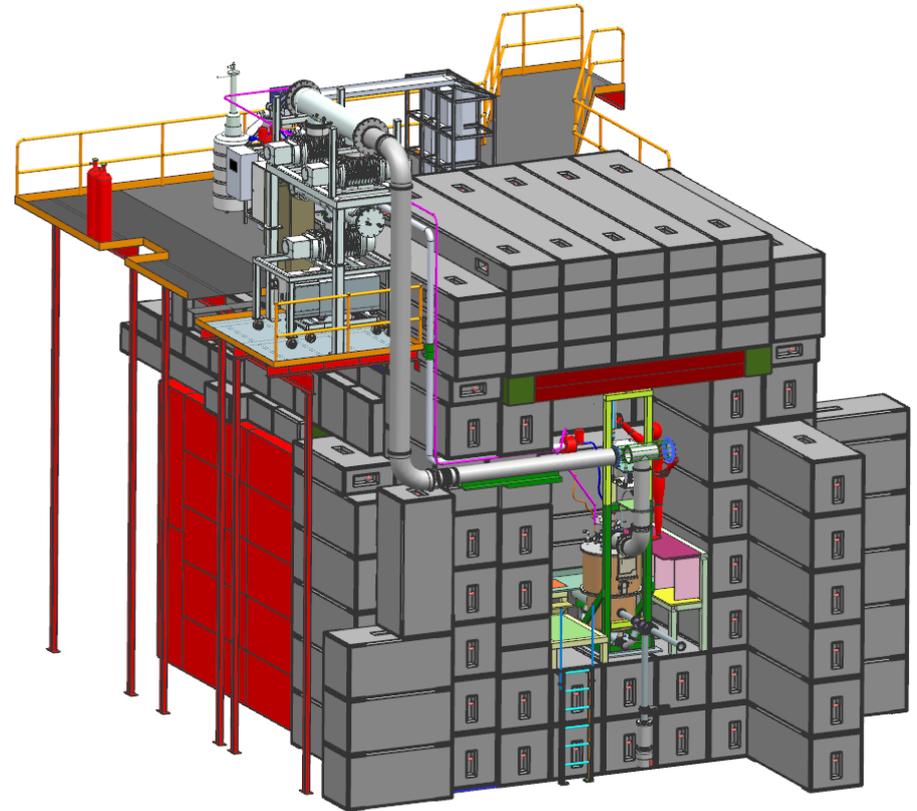

S. Kumano and Qin-Tao Song, PhysRev.D 94, 054022

The E1039 spectrometer

- The spectrometer is basically the same as the Seaquest/E906 experiment.
- New fiber scintillators are added in the station 1 and 2.
 - These will be part of the trigger to improve the z resolution; which helps in rejecting background.
 - These can also be used to construct new trigger for Dark Photon search; events from the down stream half of the FMag.

Preparing the experiment

- Beam line and target cave reconstruction are well in progress.
- Installation of polarized target is well in progress.

Summary

- The SeaQuest obtained a preliminary result on the cross-section ratio of LD2/LH2, \bar{d}/\bar{u} is still being finalized.
- E1039 will measure the single-spin asymmetry induced by Sivers function of antiquark.
- Study of transversity and contribute to tensor charge.
- Study of the tensor polarization using polarized ND3.
- Expect to take beam in Spring of 2020 with dummy target.

Stay tuned!

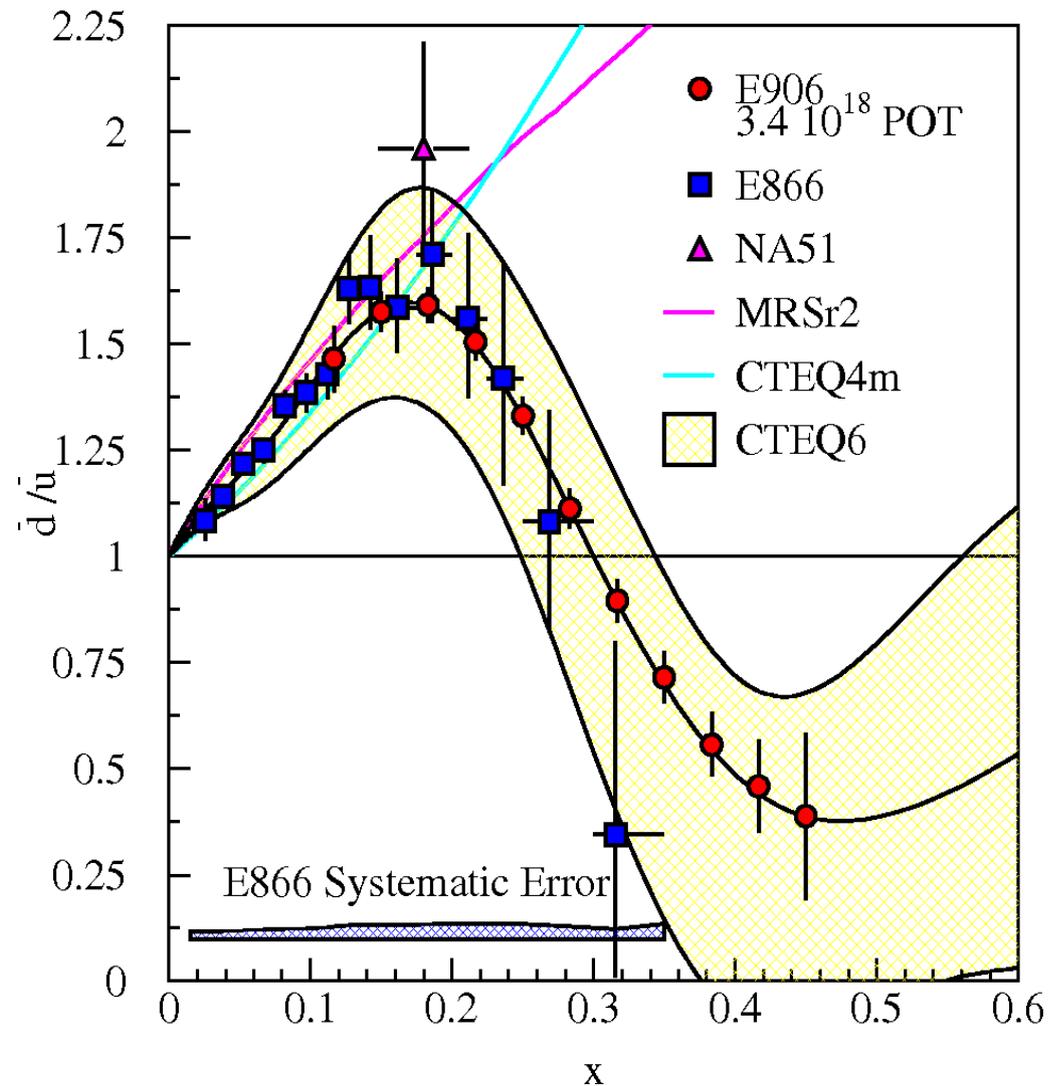

Cross-section ratio dependence on x_2

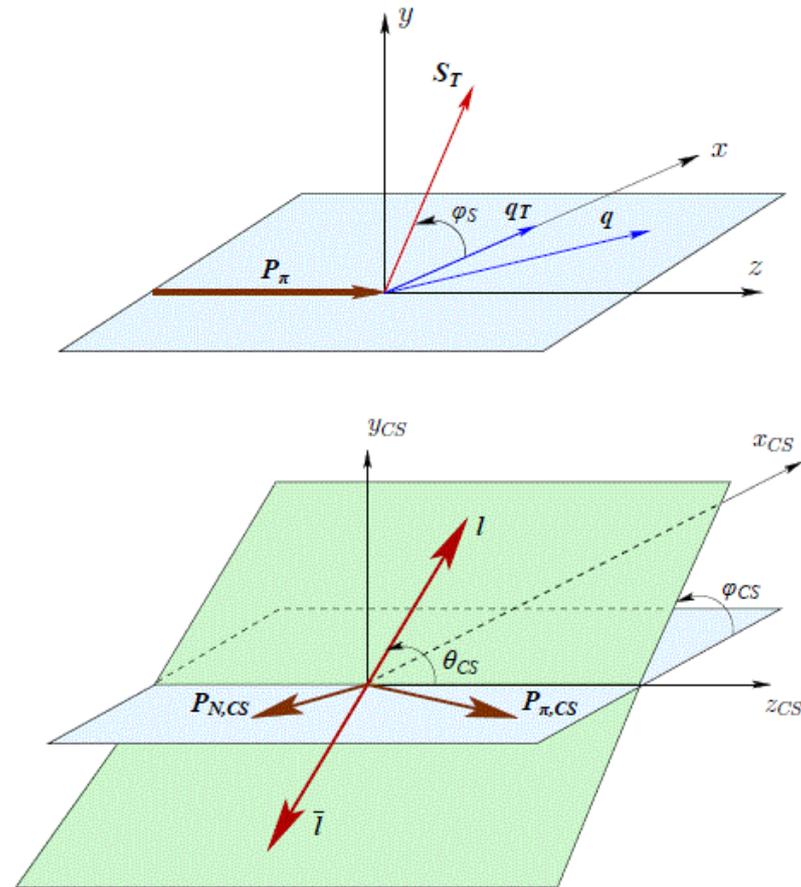

The \bar{d}/\bar{u} asymmetry

- The asymmetry has strong dependence on Bjorken x !
 - It is hard to explain the dropping in high x region!
- The SeaQuest experiment is done taking data in 2017.
- Preliminary result based on 50% of data.

Frames used by COMPASS

Tensor polarization

- Tensor polarization is available when the target particle
 - has spin = 1, such as deuteron and
 - is polarized.
- For a spin 1 particle in magnetic field,
 - Zeeman effects creates three levels, $m=+1,0,-1$; corresponding populations are p_+ , p_0 and p_- .
 - In this case there are
 - vector polarization = $p_+ - p_-$
 - tensor polarization = $(p_+ - p_0) - (p_0 - p_-) = 1 - 3 p_0$.
