
RD53B single chip card
requests

- RD53A SCC was very good and extremely useful.
- Some changes/improvements can be suggested for multiple reasons
 - Specialist and non specialist use
 - Simple default card configuration
 - Means for specialists to try out “exotic” and emergency options
 - Chip functional testing
 - Radiation tests
 - Serial powering testing
 - Chip tests with sensor (by chip community)
 - Sensor testing (by sensor community)
 - Debugging of wafer probing routines (without probe card)
 - Many new features in RD53B

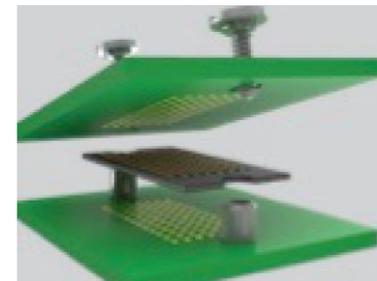

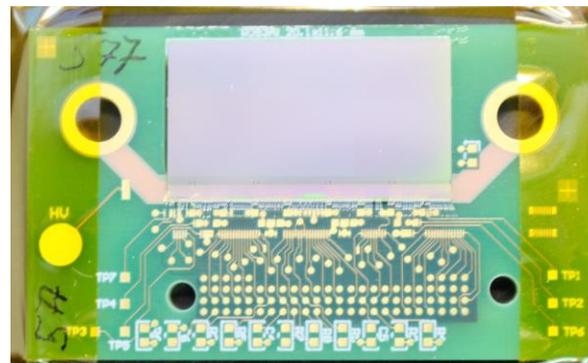

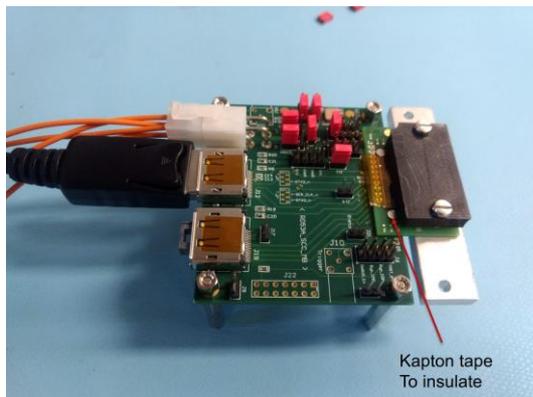

- Compatible to both ATLAS and CMS RD53B chips (Same pad frame, different chip size)
- Compatible with current test/DAQ systems (BDAQ53, Yarr, CMS tracker DAQ, ATLAS DAQ ?.)
- Keep:
 - Display port connections, Power connection
 - Cooling foot print with no components below chip and thermal vias. (where to put NTSC ?)
 - Powering options with simple jumpers
 - Short inductance between chip and decoupling caps
 - Possible to replace/decrease decoupling caps for tests of required caps (without destroying wire-bonds)
 - NTSC temp sensor (with factory calibration +/- 1°C)
 - Pt100 alternative as intrinsically calibrated
 - Test points for manual measuring with multi-meter, oscilloscope, etc.
 - Use of Samtec high speed probe connectors for control and serial links ?
 - Default external resistors, etc. for basic/easy use.
 - Simple passive card (no radiation issues)
- Minor changes/additions:
 - DIP switch for ID
 - Easy exchange of external resistors values: Iref, Voff, Reff1, Reff2, etc (small plug on card)
 - Test point to measure voltage on external Reff to verify current mirror ratio (issue in RD53A)
 - 2nd NTSC for chip NTSC input
 - Chip at edge of board (no top pad frame) as useful for double chip irradiation (low dose rate)
 - Support for DFT TBD (so can be debugged without probe card)
- Emergency options (e.g. PLL bypass, etc)
- Minimize activatable material (see CMS irradiation card)
- Additional expert flexibility with optional control/monitor plug-in card: Defined signals on connector
 - Remote control between power modes (as for wafer probe card)
 - Remote monitoring of important references, voltages, currents (as for wafer probe card)
 - Use jumpers to define if signals controlled/monitored by external control/monitor card

RD53B dream SCC ?

- Minimalistic irradiation card for sensor irradiation campaigns
 - Not powered during irradiation
 - Minimal mass/activation
 - Small
 - Plugs into adaptor card having same interfaces as SCC.
 - Test chip/sensor before and after irradiation.
 - Active use in test beams (before and after irradiation)
 - Use of Samtec interposer connector (small, high pin count, high frequency, no physical connector on irradiation card)
 - Extensively used in CMS for sensor assembly irradiations and tests
 - Designed by Rice university
 - Adapter card made as modified version of SCC.
- Common/shared development ?
 - Shared design files

RICE university
