Outline

Neutrino NSI

From EFTs to Simplified Models

Complementarity between LHC and neutrino experiments

Towards a UV complete scenario

Conclusion

Neutrino NSI

Unknown couplings involving neutrinos.

Many neutrino mass models naturally lead to NSI at some level. (see for example, B. Dev et al. (2019), K.S. Babu, B. DeV, SJ, A. Thapa (2019), Tommy Ohlsson (2012))

Potentially observable effects in neutrino oscillation experiments.

NSI effects happen in the neutrino production, propagation through matter, and the detection processes.

**Most important effect of NSI is in neutrino propagation in matter
*Wolfenstein (1978)***

Relevant for accelerator, reactor, atmospheric, solar and supernova neutrinos.

Search for NSI is complementary to the direct search for new physics at the LHC.

Neutrino NSI

$$\mathcal{L}^{eff} = \mathcal{L}_{SM} + \frac{1}{\Lambda} \delta\mathcal{L}^{d=5} + \boxed{\frac{1}{\Lambda^2} \delta\mathcal{L}^{d=6}} + \dots$$

NSI affecting
production

$$\varepsilon_{\mu\alpha}^{e\mu,P} (\bar{e}\gamma^\rho P\mu) (\bar{\nu}_\mu\gamma_\rho P_L\nu_\alpha)$$

NSI affecting
detection

$$\varepsilon_{\mu\alpha}^{ud,P} (\bar{d}\gamma^\rho Pu) (\bar{\nu}_\mu\gamma_\rho P_L l_\alpha^-)$$

NSI affecting
propagation

$$\varepsilon_{\mu\alpha}^{f,P} (\bar{f}\gamma^\rho Pf) (\bar{\nu}_\mu\gamma_\rho P_L\nu_\alpha)$$

Neutrino NSI

$$\mathcal{L}_{\text{NSI}} = -2\sqrt{2} G_F \epsilon_{\alpha\beta}^{fP} (\bar{\nu}_\alpha \gamma_\rho \nu_\beta) (\bar{f} \gamma^\rho P f)$$

Beam neutrino exp.

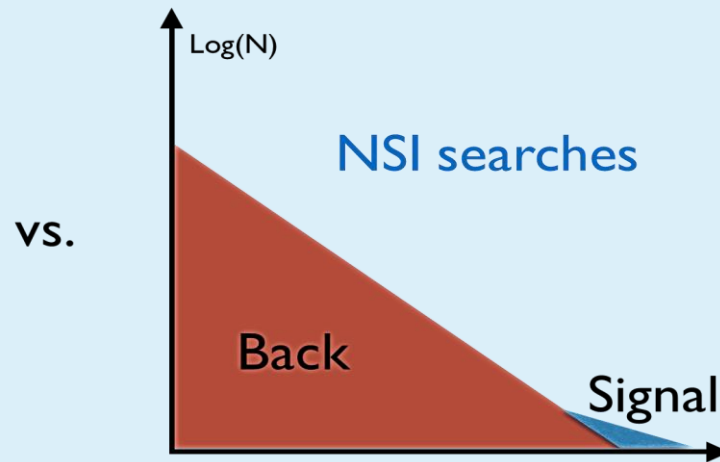

Neutrino NSI at LHC

$$\mathcal{L}_{\text{NSI}} = -2\sqrt{2} G_F \varepsilon_{\alpha\beta}^{fP} (\bar{\nu}_\alpha \gamma_\rho \nu_\beta) (\bar{f} \gamma^\rho P f)$$

Irreducible SM background

Neutrino NSI at LHC

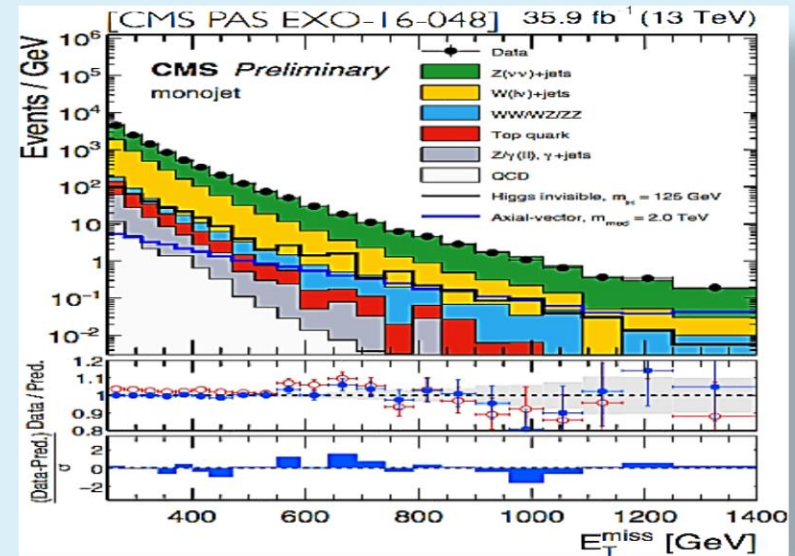

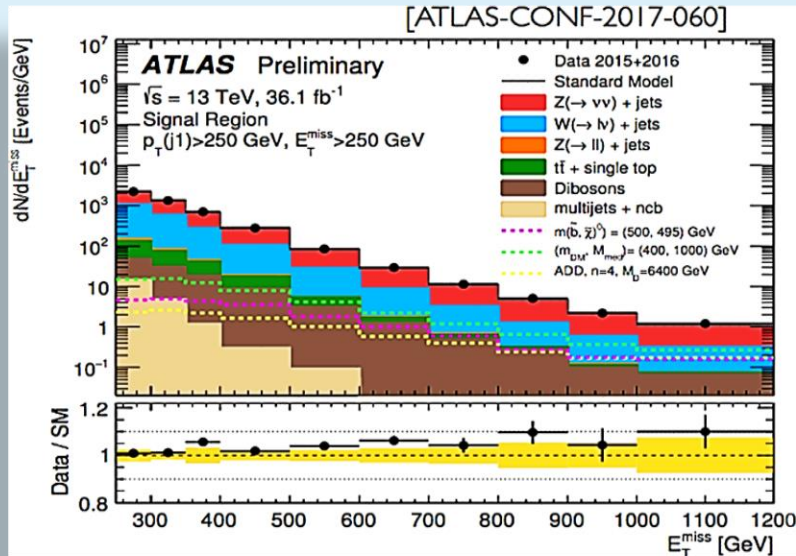

Overwhelming SM background

NSI contains both flavor-changing and flavor-diagonal interactions

Signal: small enhancement in the tail of MET distribution

Big challenge: requires precise estimation of background

Neutrino NSI at LHC

Dominant background:

- $pp \rightarrow Z (\rightarrow \nu\nu) + \text{jets} \rightarrow \text{MET} + \text{jets}$
- $pp \rightarrow W (\rightarrow l\nu) + \text{jets} \rightarrow \text{MET} + \text{jets}$ (lost lepton or hadronic taus)

Major limitation for NSI bounds: large and uncertain backgrounds. Background syst. $\sim 5\%$

New theoretical and experimental efforts are significantly suppressing this syst. constraint

Neutrino NSI at LHC

$$\sigma(pp \rightarrow j\bar{\nu}_\alpha\nu_\beta) = \sigma_{\text{SM}} + \varepsilon\sigma_{\text{int}} + \varepsilon^2\sigma_{\text{NSI}}$$

NSI contains both flavor-changing and flavor-diagonal interactions

- Flavor-changing - No SM analog
- Flavor-diagonal - Interfere with SM background (can display non-trivial differences to DM scenario)

We find the interference effect to be negligible in the region of interest for the LHC sensitivity. Therefore, the diagonal and non-diagonal NSIs result in equivalent bounds at LHC.

Signal: small enhancement in the tail of MET distribution

arXiv:1711.03301 [hep-ex]

Following the recent 13 TeV ATLAS monojet study, we define jets with the anti- k_t jet algorithm and radius parameter $R = 0.4$, $p_{Tj} > 30$ GeV and $|\eta| < 2.8$

Events with identified electrons with $p_T > 20$ GeV or muons $p_T > 10$ GeV in the final state are vetoed.

To suppress the Z+jets and W+jets backgrounds, the events are selected with missing $E_T > 250$ GeV recoiling against a leading jet with $p_{Tj1} > 250$ GeV, $|\eta_{j1}| < 2.4$, and azimuthal separation $\Delta\phi(j_1, \sim p_{T,\text{miss}}) > 0.4$.

Events with more than four jets are vetoed.

Experimental bounds from di-jet searches:

Eur. Phys. J. C78 no. 9, (2018) 789, arXiv:1803.08030 [hep-ex], etc. (see arXiv: 2003.03383 and references therein)

From EFTs to Simplified Models

K.S. Babu, D. Gonçalves, SJ, P.A.N. Machado (2020)

P. Coloma, I. Esteban, M. C. Gonzalez-Garcia, and M. Maltoni (2019)

NSIs are generally parametrized in the EFT framework as:

$$\mathcal{L}_{\text{NSI}} = -2\sqrt{2}G_F\epsilon_{\alpha\beta}^{fY} \left(\bar{\nu}^\alpha \gamma_\mu \nu^\beta \right) \left(\bar{f} \gamma^\mu P_Y f \right)$$

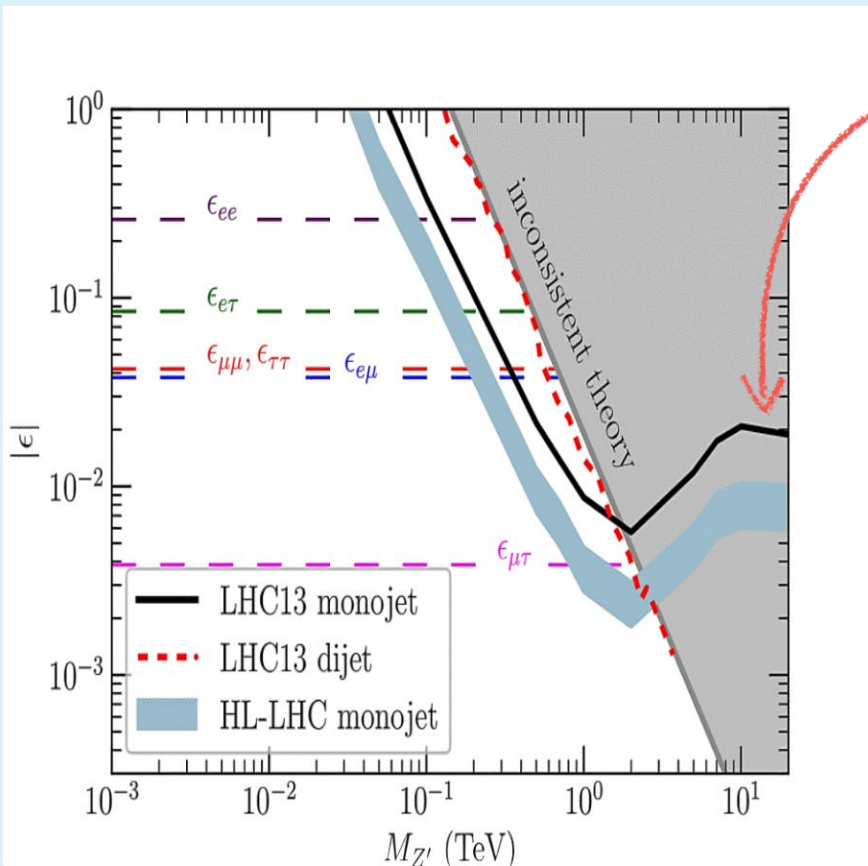

Adopting a simplified model approach, we parametrize the NSI as:

$$\mathcal{L}_{\text{NSI}}^{\text{Simp}} = \left(g_\nu^{\alpha\beta} \bar{\nu}_\alpha \gamma^\mu P_L \nu_\beta + g_{q_i}^Y \bar{q}_i \gamma^\mu P_Y q_i \right) Z'_\mu$$

Neutrino NSIs arise in the simplified model as:

$$\epsilon_{\alpha\beta}^u = \epsilon_{\alpha\beta}^d \equiv \epsilon_{\alpha\beta} = \frac{(g_\nu)_{\alpha\beta} g_{u,d}^V}{2\sqrt{2}G_F M_{Z'}^2}$$

Validity of this EFT at the LHC

K.S. Babu, D. Gonçalves, **SJ**, P.A.N. Machado (2020)

We can identify the EFT regime for the LHC when the mass of the mediator is much above the scale of the process involved.

For any fixed ratio $\Gamma_{Z'}/M_{Z'}$, we can write the following inequality

$$|\epsilon| \leq \frac{\sqrt{3}\pi}{\sqrt{N}G_F M_{Z'}^2} \frac{\Gamma_{Z'}}{M_{Z'}}$$

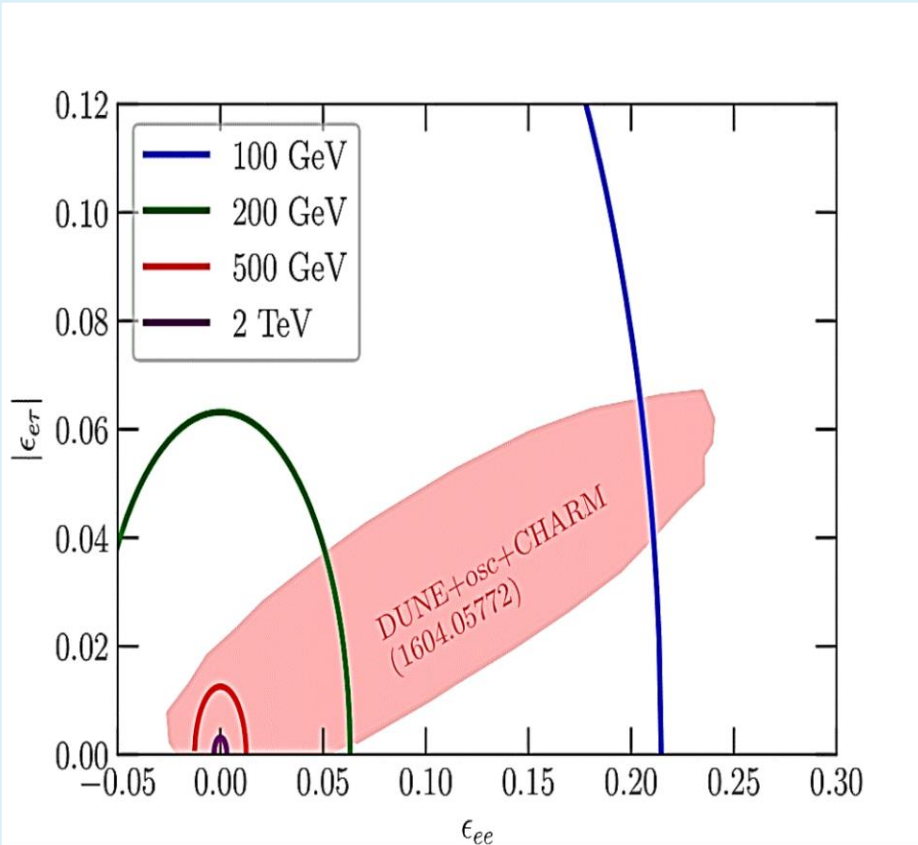

This constraint originates from the fact that the total width of the Z' should be larger than the partial widths to $q_i q_i$ and $\nu\nu$:

$$\Gamma_{Z'} \geq M_{Z'} / (24\pi) \left(g_\nu^2 + 3N \left\{ (g_u^V)^2 + (g_d^V)^2 \right\} \right)$$

Considering narrower Z' makes the constraint stronger, while broader Z' implies non-perturbativity

Traditional EFT analyses at the LHC using four-fermion operators will typically not be valid, at least having simple/minimal UV completions in mind.

Complementarity between LHC and neutrino experiments

K.S. Babu, D. Gonçalves, **SJ**, P.A.N. Machado (2020)
P. Coloma et al. (2016) , J. Liao et al. (2016)

Differently from the LHC, the effects of NSIs in neutrino oscillations strongly depend on the flavor structure of the NSI and the oscillation channel being studied.

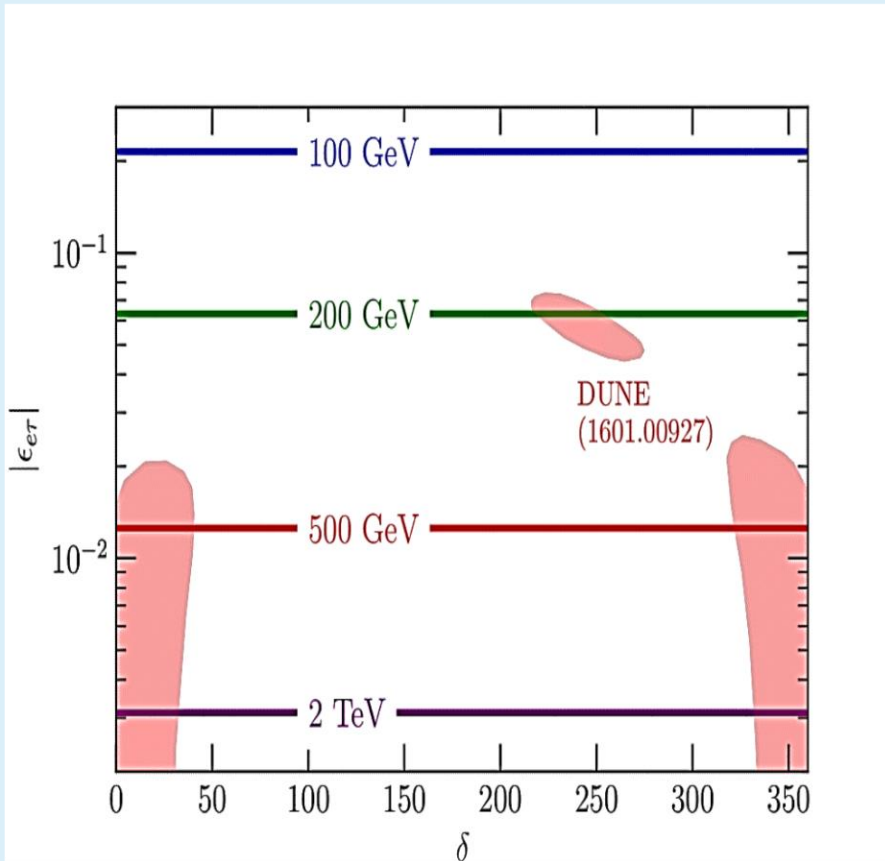

The effects of different NSIs and/or variations of the standard oscillation parameters can, in some cases, compensate each other and lead to well known degeneracies.

Disentangling those is a difficult task at neutrino facilities.

In contrast, the mono-jet signal at the LHC, does not distinguish between different choices of flavors i.e., they all lead to the same observables.

Besides constraining the currently allowed NSI parameter space, this feature can be further exploited to break relevant degeneracies.

Complementarity between LHC and neutrino experiments

K.S. Babu, D. Gonçalves, SJ, P.A.N. Machado (2020)
P. Coloma et al. (2016) , J. Liao et al. (2016)

The LHC sensitivity displays a strong dependence on the mediator mass, but it is free of parameter degeneracies. Neutrino oscillation measurements, on the other hand, exhibit the opposite behavior: significant degeneracies and no mediator mass dependence.

The matter potential induced when neutrinos travel through a medium is not affected by a diagonal, universal contribution (as this just induces an overall phase shift on the neutrino state). On the other hand, LHC data is sensitive to each and all NSI parameters independently.

Neutrino oscillations are not sensitive to axial interactions, while LHC data is sensitive to both vector and axial new physics contributions.

All these features show the synergies between oscillation measurements and collider data on probing new physics in the neutrino sector.

Towards a UV complete scenario

K.S. Babu, D. Gonçalves, **SJ**, P.A.N. Machado (2020)
K.S. Babu, A. Friedland, P.A.N. Machado, I. Mocioiu (2017)
F. Elahi and A. Martin (2019)

Any UV complete model of neutrino NSI is expected to provide a more extensive phenomenology, especially since neutrinos are in the same $SU(2)_L$ doublet as charged leptons.

In this UV completion the $B - L$ number is gauged, but only for the third family.

Heavy mediators are strongly constrained by LHC data.

Low mediators constrained by low-energy experiments.

Towards a UV complete scenario

K.S. Babu, D. Gonçalves, **SJ**, P.A.N. Machado (2020)

Low energy constraints, dedicated LHC searches, and missing energy signatures provide strong constraints for different masses of the mediator.

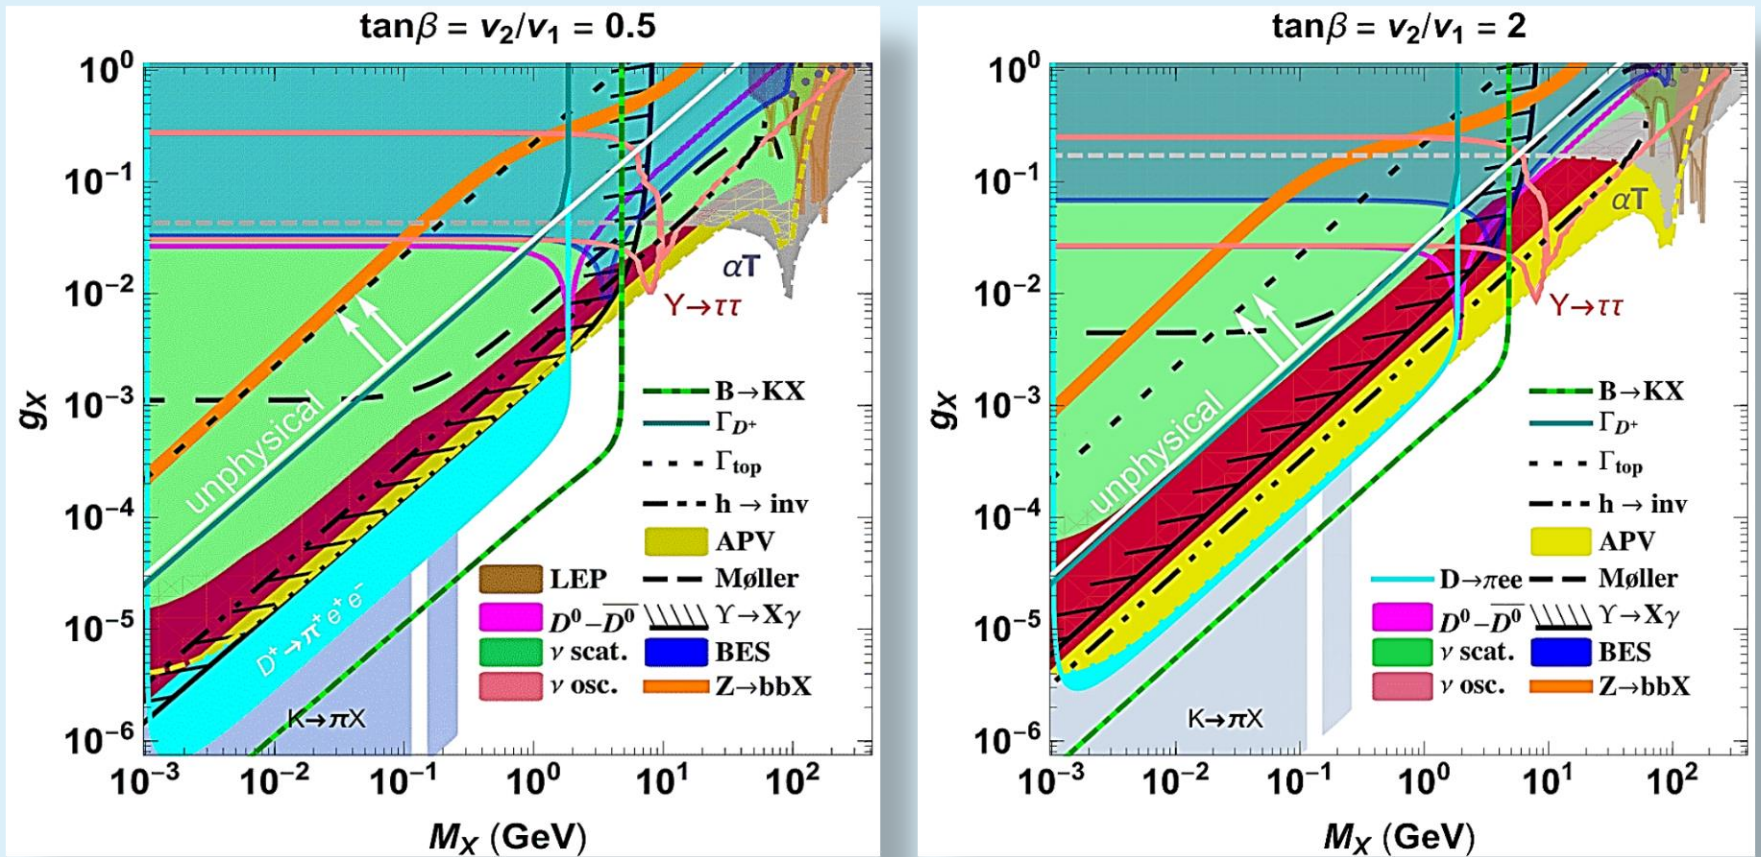

For masses below about 10 GeV, low energy observables tend to dominate.

In the intermediate regime 10 – 100 GeV, dedicated searches for visible signatures at the LHC become more relevant.

Finally, from 0.1 – 1 TeV LHC mono-jet searches, low energy observables and electroweak precision observables (up to the T parameter model dependence) play the leading role.

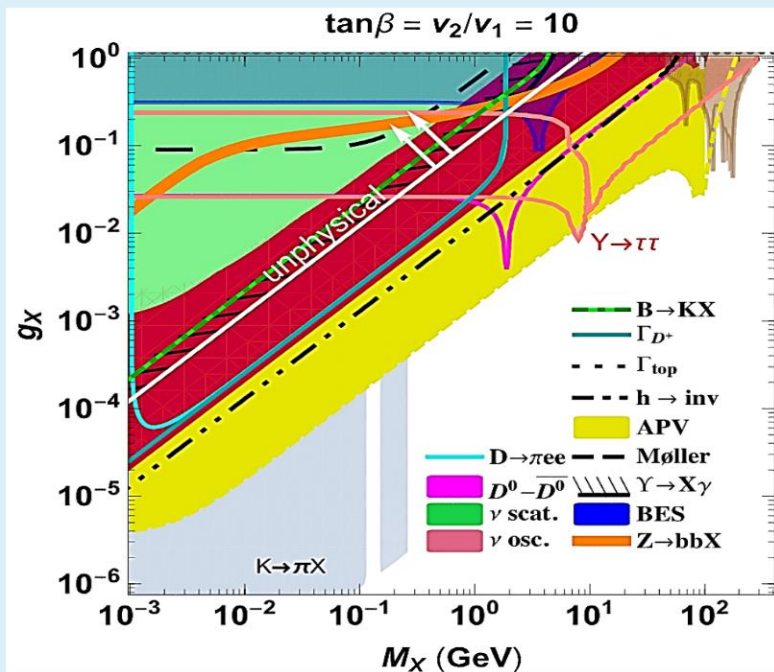

This makes manifest the complementarities among collider data, oscillation measurements, and other low energy observables.

Towards a UV complete scenario

K.S. Babu, D. Gonçalves, SJ, P.A.N. Machado (2020)

Towards a UV complete scenario

K.S. Babu, D. Gonçalves, **SJ**, P.A.N. Machado (2020)

For other collider studies on NSI: See A. Friedland, M. L. Graesser, I. M. Shoemaker, and L. Vecchi (2011), D. Choudhury, K. Ghosh, and S. Niyogi (2018), T. Han, J. Liao, H. Liu, and D. Marfatia (2019) etc.

Summary

We have explored the complementarity between neutrino experiments and LHC searches in probing neutrino NSI.

It covers the full span of theory frameworks: effective field theories, simplified models, and an illustrative UV completion.

The LHC sensitivities to NSIs display relevant synergies to oscillation results. Namely,

i) the breakdown of degeneracies among NSI and oscillation parameters,

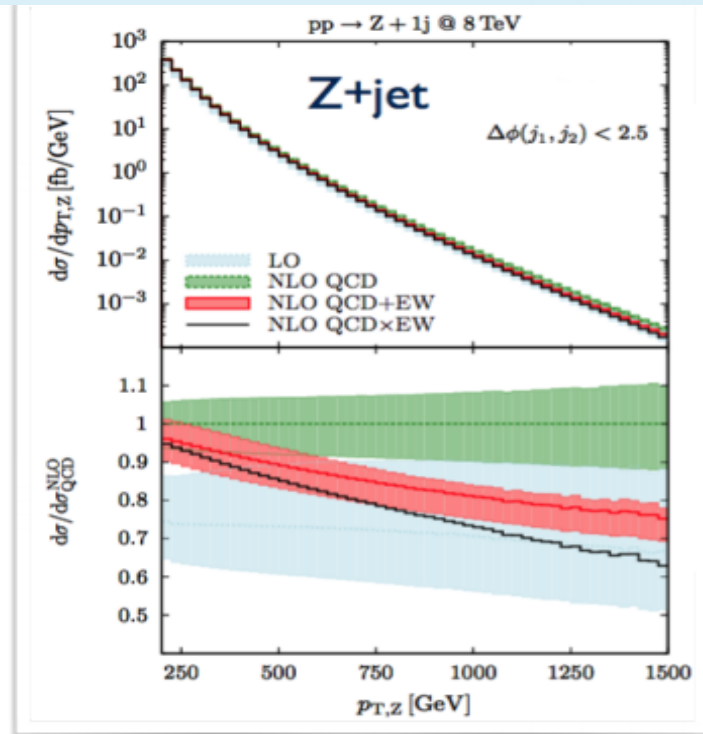

and ii) sensitivity to new phenomenological signatures at the LHC.

As a by-product of our analysis, we have shown that the use of EFT at the LHC in estimating sensitivity to NSIs is not generally theoretically consistent.

Monojets: systematic uncertainties

Lindert, Pozzorini, et al '17

- **QCD corrections:**
 Moderate and stable
 NLO uncert. 5-10%

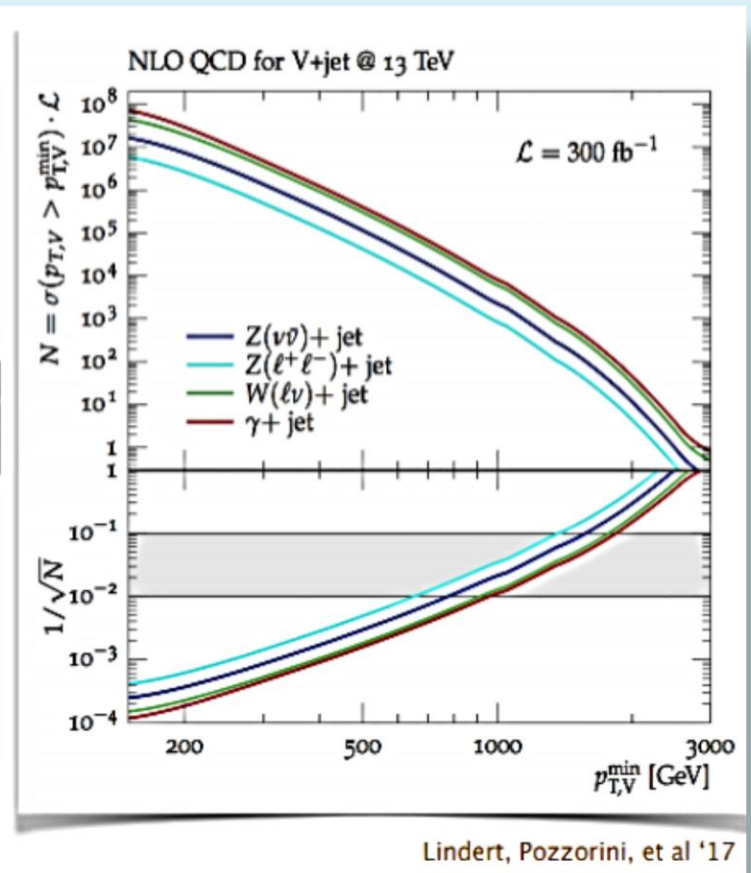

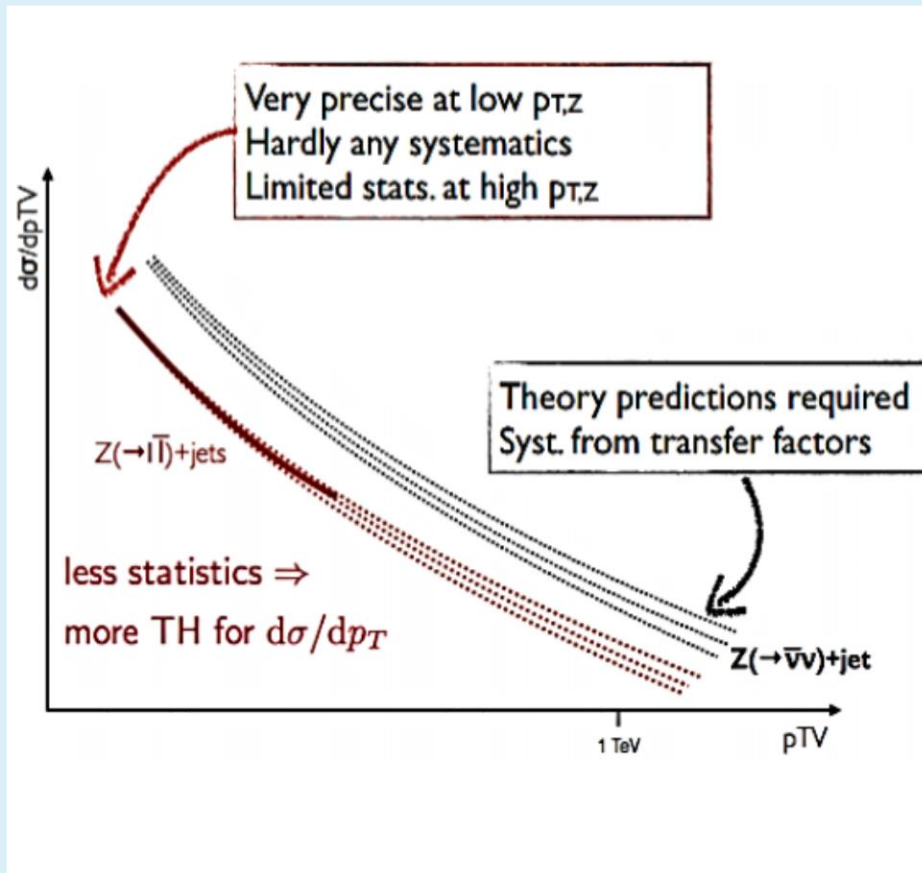

- **EW corrections:**
 EW corrections > QCD corrections for $p_{T,Z} > 350$ GeV

- ➔ Given that **QCD** and **EW** corrections are large, mixed QCD-EW corrections have to be considered

- State of the art of MC simulation: NNLO **QCD** + NLO **EW**
 “Simply” accounting for higher orders is not enough. Uncertainties $O(5\%)$
 We need new ingredients to control the errors!
