A natural mechanism for a SM-like Higgs boson in the 2HDM without decoupling

Howard E. Haber
December 3, 2021
Outline

1. LHC reveals a Standard Model (SM)-like Higgs boson

2. The Higgs alignment limit
   - Exact vs. approximate alignment
   - Symmetry-based (natural) approach to Higgs alignment
   - Deviating from exact alignment due to soft-symmetry breaking

3. Extending the symmetry to the Yukawa sector

Nine years after the discovery of the Higgs boson, the data from Runs 1 and 2 of the LHC are well described by the Standard Model.

Cross sections times branching fraction for $ggF$, vector boson fusion (VBF), $VH$ and $ttH+tH$ production in each relevant decay mode, normalized to their Standard Model (SM) predictions. The values are obtained from a simultaneous fit to all channels. The black error bars, blue boxes and yellow boxes show the total, systematic, and statistical uncertainties in the measurements, respectively. The gray bands show the theory uncertainties on the predictions. The level of compatibility between the measurement and the SM prediction corresponds to a $p$-value of $p_{SM}=79\%$, computed using the procedure outlined in the text with 21 degrees of freedom.
The best fit estimates for the reduced coupling modifiers extracted for fermions and weak bosons from the resolved $\kappa$-framework compared to their corresponding prediction from the SM. The error bars represent 68% CL intervals for the measured parameters. In the lower panel, the ratios of the measured coupling modifiers values to their SM predictions are shown.
Nevertheless, given the current precision of the Higgs data, the possibility that the Higgs sector contains more than one physical scalar cannot be excluded.

Indeed, the structure of the Standard Model (SM) is far from being of minimal form. For example, there are three generations of quarks and leptons whereas one generation would have been sufficient (“Who ordered that?”). So why shouldn’t the scalar sector be non-minimal as well?
Why is the observed Higgs boson SM-like?

- There is no extended Higgs sector.

- All other scalars (apart from the SM-like Higgs boson) are very heavy
  - This is the decoupling limit.

- A neutral scalar field with the tree-level properties of the SM Higgs boson is an approximate mass eigenstate (due to suppressed mixing with other neutral scalar fields of the extended Higgs sector).
  - This is the Higgs alignment limit.
  - The other physical scalars of the model may or may not be significantly heavier than the SM Higgs boson. That is, the decoupling limit is a special case of the Higgs alignment limit.
The Higgs field alignment limit: approaching the SM Higgs boson

Consider an extended Higgs sector with $n$ hypercharge-one Higgs doublets $\Phi_i$ and $m$ additional singlet Higgs fields $\phi_i$.

After minimizing the scalar potential, we assume that only the neutral Higgs fields acquire vacuum expectation values (in order to preserve $U(1)_{EM}$),

$$\langle \Phi^0_i \rangle = v_i / \sqrt{2}, \quad \langle \phi^0_j \rangle = x_j.$$ 

Note that $v^2 \equiv \sum_i |v_i|^2 = 4m_W^2 / g^2 = (246 \, \text{GeV})^2$. 
The Higgs basis

Define new linear combinations of the hypercharge-one doublet Higgs fields (the so-called Higgs basis). In particular,

\[
H_1 = \left( \begin{array}{c} H_1^+ \\ H_1^0 \end{array} \right) = \frac{1}{v} \sum_i v_i \Phi_i, \quad \langle H_1^0 \rangle = v/\sqrt{2},
\]

and \( H_2, H_3, \ldots, H_n \) are the other linear combinations of doublet scalar fields such that \( \langle H_i^0 \rangle = 0 \) (for \( i = 2, 3, \ldots, n \)).

That is \( H_1^0 \) is aligned in field space with the direction of the Higgs vacuum expectation value (vev). Thus, if \( \sqrt{2} \text{Re}(H_1^0) - v \) is a mass-eigenstate, then the tree-level couplings of this scalar to itself, to gauge bosons and to fermions are precisely those of the SM Higgs boson, \( h^0 \). This is the exact alignment limit.
A natural SM-like Higgs boson in an extended Higgs sector

- The naturalness of the SM-like Higgs boson mass will not be addressed here.

- The decoupling limit explanation of the SM-like Higgs boson is natural to the extent that the low-energy effective theory simply reduces to the SM.

- The central question of this talk is whether there is a natural mechanism that can produce approximate Higgs alignment without decoupling. The low energy effective theory will then contain the SM-like Higgs boson along with additional scalar states whose masses are not significantly larger than a few hundred GeV.

Naturalness à la 't Hooft: guaranteed by a symmetry that is either exact or is broken by soft symmetry breaking terms of positive mass dimension (i.e., by terms of dimension 3 or less in the Lagrangian).
The Higgs alignment limit of the 2HDM

Define the scalar doublet fields of the Higgs basis,

\[ \mathcal{H}_1 = \begin{pmatrix} \mathcal{H}_1^+ \\ \mathcal{H}_1^0 \end{pmatrix} \equiv c_\beta \Phi_1 + s_\beta e^{-i\xi} \Phi_2, \quad \mathcal{H}_2 = \begin{pmatrix} \mathcal{H}_2^+ \\ \mathcal{H}_2^0 \end{pmatrix} \equiv e^{i\eta} (-s_\beta e^{i\xi} \Phi_1 + c_\beta \Phi_2), \]

such that \( \langle \mathcal{H}_1^0 \rangle = v/\sqrt{2} \) and \( \langle \mathcal{H}_2^0 \rangle = 0 \). The Higgs basis is uniquely defined up to an overall rephasing that is parameterized by the phase angle \( \eta \).

The neutral scalar \( \mathcal{H}_1^0 \) is aligned in field space with the vacuum expectation value \( v \). If \( \sqrt{2} \text{Re} \mathcal{H}_1^0 - v \) were a mass eigenstate, then its tree-level properties would coincide with those of the SM Higgs boson.

In the Higgs basis, the scalar potential is given by:

\[ V = Y_1 \mathcal{H}_1^\dagger \mathcal{H}_1 + Y_2 \mathcal{H}_2^\dagger \mathcal{H}_2 + [Y_3 e^{-i\eta} \mathcal{H}_1^\dagger \mathcal{H}_2 + \text{h.c.}] + \frac{1}{2} Z_1 (\mathcal{H}_1^\dagger \mathcal{H}_1)^2 \]
\[ + \frac{1}{2} Z_2 (\mathcal{H}_2^\dagger \mathcal{H}_2)^2 + Z_3 (\mathcal{H}_1^\dagger \mathcal{H}_1)(\mathcal{H}_2^\dagger \mathcal{H}_2) + Z_4 (\mathcal{H}_1^\dagger \mathcal{H}_2)(\mathcal{H}_2^\dagger \mathcal{H}_1) \]
\[ + \left\{ \frac{1}{2} Z_5 e^{-2i\eta} (\mathcal{H}_1^\dagger \mathcal{H}_2)^2 + [Z_6 e^{-i\eta} (\mathcal{H}_1^\dagger \mathcal{H}_1) + Z_7 e^{-i\eta} (\mathcal{H}_2^\dagger \mathcal{H}_2)] \mathcal{H}_1^\dagger \mathcal{H}_2 + \text{h.c.} \right\}. \]

Minimize the scalar potential: \( Y_1 = -\frac{1}{2} Z_1 v^2 \) and \( Y_3 = -\frac{1}{2} Z_6 v^2 \).

**Remark:**

Exact Higgs alignment \( \iff Z_6 = 0 \) (and \( Y_3 = 0 \) via the scalar potential minimum conditions), which implies no \( \mathcal{H}_1^0 - \mathcal{H}_2^0 \) mixing.

Only the terms highlighted in red can yield an \( \mathcal{H}_1^\dagger \mathcal{H}_2 + \text{h.c.} \) contribution to the quadratic terms of the scalar potential after imposing \( \langle \mathcal{H}_1^0 \rangle = v/\sqrt{2} \) and \( \langle \mathcal{H}_2^0 \rangle = 0 \).
Approximate Higgs alignment in the CP-conserving 2HDM

With respect to Higgs basis states, \( \{ \sqrt{2} \text{Re} \, H_1^0 - v, \sqrt{2} \text{Re} \, H_2^0 \} \),

\[
\mathcal{M}_H^2 = \begin{pmatrix} Z_1 v^2 & Z_6 v^2 \\ Z_6 v^2 & m_A^2 + Z_5 v^2 \end{pmatrix}, \quad \text{where } Z_5, Z_6 \in \mathbb{R}.
\]

The CP-even Higgs bosons are \( h \) and \( H \) with \( m_h \leq m_H \).

Approximate Higgs alignment arises in two limiting cases:

1. \( m_A^2 \gg (Z_1 - Z_5)v^2 \). This is the \textit{decoupling limit}, where \( h \) is SM-like and \( m_A^2 \sim m_H^2 \sim m_{H^\pm}^2 \gg m_h^2 \sim Z_1 v^2 \).

2. \( |Z_6| \ll 1 \). Then, \( h \) is SM-like if \( m_A^2 + (Z_5 - Z_1)v^2 > 0 \); otherwise, \( H \) is SM-like. \( \rightarrow \) \textit{Alignment without decoupling}. 
In particular, the CP-even neutral scalar mass eigenstates are:

\[
\begin{pmatrix}
H \\
h
\end{pmatrix} = \begin{pmatrix}
c_{\beta - \alpha} & -s_{\beta - \alpha} \\
s_{\beta - \alpha} & c_{\beta - \alpha}
\end{pmatrix} \begin{pmatrix}
\sqrt{2} \text{ Re } H_1^0 - v \\
\sqrt{2} \text{ Re } H_2^0
\end{pmatrix},
\]

where \(c_{\beta - \alpha} \equiv \cos(\beta - \alpha)\) and \(s_{\beta - \alpha} \equiv \sin(\beta - \alpha)\) are defined in terms of the mixing angle \(\alpha\) that diagonalizes the CP-even Higgs squared-mass matrix when expressed in the \(\Phi_1 - \Phi_2\) basis of scalar fields, \(\{\sqrt{2} \text{ Re } \Phi_1^0 - v_1, \sqrt{2} \text{ Re } \Phi_2^0 - v_2\}\), and \(\tan \beta \equiv v_2 / v_1\).

Since the SM-like Higgs boson must be approximately \(\sqrt{2} \text{ Re } H_1^0 - v\), it follows that

- \(h\) is SM-like if \(|c_{\beta - \alpha}| \ll 1\) (Higgs alignment with or without decoupling, depending on the value of \(m_A\)),

- \(H\) is SM-like if \(|s_{\beta - \alpha}| \ll 1\) (Higgs alignment without decoupling).
If $h$ is SM-like

Then, $m_h^2 \simeq Z_1 v^2$ (i.e., $Z_1 \simeq 0.26$) and

$$|c_{\beta-\alpha}| = \frac{|Z_6|v^2}{\sqrt{(m_H^2 - m_h^2)(m_H^2 - Z_1 v^2)}} \simeq \frac{|Z_6|v^2}{m_H^2 - m_h^2} \ll 1,$$

That is, $h$ is SM-like either

- in the decoupling limit where $m_H \gg m_h$,

or

- in the alignment limit without decoupling where $m_H \sim \mathcal{O}(v)$ and $|Z_6| \ll 1$. 
Regions excluded by fits to the measured rates of the productions and decay of the Higgs boson (assumed to be h of the 2HDM). Contours at 95% CL. The observed best-fit values for $\cos(\beta - \alpha)$ are -0.006 for the Type-I 2HDM and 0.002 for the Type-II 2HDM. Taken from ATLAS Collaboration, ATLAS-CONF-2021-053 (2 November 2021).
Achieving exact Higgs alignment in the 2HDM

The inert doublet model (IDM): There is a $\mathbb{Z}_2$ symmetry in the Higgs basis such that $\mathcal{H}_2 \to -\mathcal{H}_2$ is the only $\mathbb{Z}_2$-odd field. Then $Z_6 = 0$, and tree-level alignment is exact. Deviations from SM behavior can appear at loop level due to the virtual exchange of the scalar states that reside in $\mathcal{H}_2$.

Approximate Higgs alignment without decoupling

- Is this the result of an accidental choice of model parameters?

- Is this the result of a scalar potential that exhibits an exact symmetry at a very high energy scale that is not respected by the full Lagrangian, thereby generating deviations from exact alignment at the electroweak scale via renormalization group evolution?\(^2\)

- Is this a consequence of an approximate (softly-broken) symmetry at the electroweak scale? \textbf{Not possible in the IDM without additional symmetries.}

Symmetries of the 2HDM bosonic sector

The gauge covariant kinetic energy terms of the scalar fields are invariant under global U(2) transformations, $\Phi \rightarrow U\Phi$.

The 2HDM scalar potential in the $\Phi$-basis is given by,

$$\mathcal{V}(\Phi) = m_{11}^2 \Phi_1^\dagger \Phi_1 + m_{22}^2 \Phi_2^\dagger \Phi_2 - [m_{12}^2 \Phi_1^\dagger \Phi_2 + \text{h.c.}] + \frac{1}{2} \lambda_1 (\Phi_1^\dagger \Phi_1)^2$$

$$+ \frac{1}{2} \lambda_2 (\Phi_2^\dagger \Phi_2)^2 + \lambda_3 (\Phi_1^\dagger \Phi_1)(\Phi_2^\dagger \Phi_2) + \lambda_4 (\Phi_1^\dagger \Phi_2)(\Phi_2^\dagger \Phi_1)$$

$$+ \left\{ \frac{1}{2} \lambda_5 (\Phi_1^\dagger \Phi_2)^2 + [\lambda_6 (\Phi_1^\dagger \Phi_1) + \lambda_7 (\Phi_2^\dagger \Phi_2)] \Phi_1^\dagger \Phi_2 + \text{h.c.} \right\} .$$

After minimizing the scalar potential, $\langle \Phi_1^0 \rangle = v c_\beta / \sqrt{2}$ and $\langle \Phi_2^0 \rangle = v s_\beta e^{i\xi} / \sqrt{2}$,

where $v \equiv 2m_W / g = 246$ GeV, $s_\beta \equiv \sin \beta$ and $c_\beta \equiv \cos \beta$, with $0 \leq \beta \leq \frac{1}{2} \pi$.

The $\Phi$-basis is meaningful once a particular (global) symmetry [e.g., a subgroup of U(2)] is imposed.
Family and GCP symmetries of the 2HDM bosonic sector

Higgs family symmetries\(^3\)

\[ \mathbb{Z}_2 : \quad \Phi_1 \rightarrow \Phi_1, \quad \Phi_2 \rightarrow -\Phi_2 \]

\[ \Pi_2 : \quad \Phi_1 \leftrightarrow \Phi_2 \]

\[ U(1)_{PQ} \text{ [Peccei-Quinn]} : \quad \Phi_1 \rightarrow e^{-i\theta} \Phi_1, \quad \Phi_2 \rightarrow e^{i\theta} \Phi_2 \]

\[ SO(3) : \quad \Phi_a \rightarrow U_{ab} \Phi_b, \quad U \in U(2)/U(1)_Y \]

Generalized CP (GCP) transformations

GCP1 : \quad \Phi_1 \rightarrow \Phi_1^*, \quad \Phi_2 \rightarrow \Phi_2^* \\

GCP2 : \quad \Phi_1 \rightarrow \Phi_2^*, \quad \Phi_2 \rightarrow -\Phi_1^* \\

GCP3 : \quad \Phi_1 \rightarrow \Phi_1^* c_\theta + \Phi_2^* s_\theta, \quad \Phi_2 \rightarrow -\Phi_1^* s_\theta + \Phi_2^* c_\theta, \quad \text{for any } 0 < \theta < \frac{1}{2} \pi \\

where \( c_\theta \equiv \cos \theta \) and \( s_\theta \equiv \sin \theta \).

\(^3\)Note that custodial symmetries are not symmetries of the gauge covariant scalar kinetic energy terms.
Possible symmetries of the 2HDM bosonic sector

A complete classification of possible Higgs family and generalized CP symmetries of the scalar potential (in the $\Phi$-basis) has been obtained.\(^4\)

Note that $\Pi_2 \iff \mathbb{Z}_2$ symmetry in a different $\Phi'$-basis; $\mathbb{Z}_2 \otimes \Pi_2 \iff$ GCP2 in a different basis; $U(1)\otimes\Pi_2 \iff$ GCP3 in a different basis, where $\Phi' = V\Phi$ for a suitably chosen $V$.

Symmetry origin for exact Higgs alignment

In the $\Phi$-basis, $\langle \Phi_1^0 \rangle = v c_\beta / \sqrt{2}$ and $\langle \Phi_2^0 \rangle = v s_\beta e^{i \xi} / \sqrt{2}$. The scalar potential parameters in this basis are related to the corresponding Higgs basis parameters; e.g.,

$$Y_3 = \left[ \frac{1}{2} (m_{22}^2 - m_{11}^2) s_\beta - \text{Re}(m_{12}^2 e^{i \xi}) c_\beta - i \text{Im}(m_{12}^2 e^{i \xi}) \right] e^{-i \xi}.$$  

If $m_{11}^2 = m_{22}^2$ and $m_{12}^2 = 0$, then $Y_3 = 0$, independently of the choice of $\beta$ and $\xi$. The scalar potential minimum condition ($Y_3 = -\frac{1}{2} Z_6 v^2$) then yields $Z_6 = 0$, i.e. exact Higgs alignment.\(^5\)

Note: if $Y_3 = 0$ by virtue of a particular choice of $\beta$ and $\xi$, then the resulting model is simply the IDM.

Exact Higgs alignment arises when the following symmetries of the 2HDM scalar potential are unbroken.

<table>

As previously noted, $\mathbb{Z}_2 \otimes \Pi_2$ and U(1)$\otimes\Pi_2$ are not independent symmetries, since a change of basis can be performed in each case to a new basis in which the GCP2 and GCP3 symmetries, respectively, are manifestly realized.

However, it is remarkable that in many cases, exact alignment is preserved even if the above symmetries are softly broken. **In all such cases, exact Higgs alignment is achieved in the inert limit where $Y_3 = Z_6 = Z_7 = 0**. A complete classification of 2HDM scalar potentials with Higgs alignment due to a symmetry has been obtained.
Approximate Higgs alignment due to soft symmetry breaking

In the models below, $Z_6 \neq 0$ but can be “naturally” small.

Has natural approximate Higgs alignment been successfully achieved?

Only if the softly-broken symmetry can be extended to the entire model Lagrangian.

- The scalar gauge covariant kinetic energy term conserves CP and is U(2)-invariant, which contains all the family symmetries previously considered.

- The Yukawa interactions do not respect the GCP2 and GCP3 symmetries.

- To extend the GCP2 and GCP3 symmetries to the Yukawa sector, we shall add vector-like top (and bottom) quark partners to the Standard Model. These symmetries will be broken softly by vector-like top mass parameters, which also provides a mechanism for generating $m_{11}^2 \neq m_{22}^2$ and $m_{12}^2 \neq 0$. 
The 2HDM with a GCP3-symmetric scalar potential can be realized in another basis as a $U(1) \otimes \Pi_2$ symmetry, where

$$m_{11}^2 = m_{22}^2, \quad \lambda_1 = \lambda_2, \quad m_{12}^2 = \lambda_5 = \lambda_6 = \lambda_7 = 0.$$

To extend this symmetry to the Yukawa sector, we introduce vector-like fermions $U$ and $\overline{U}$. SM two-component fermions are denoted by lower case letters (e.g. doublet fields $q = (u, d)$ with $Y = 1/3$ and singlet fields $\bar{u}$ with $Y = -4/3$); vector-like singlet two-component fermions by upper case letters. Note that $Y_{\bar{u}} = Y_{\overline{U}} = -Y_U$. Under the symmetries,$^6$

$^6$The down-type quarks and leptons can also be included by introducing the appropriate vector-like fermions, in which case the Type-I, II, X or Y Higgs-fermion Yukawa couplings can be realized.
The Yukawa couplings consistent with the $U(1) \otimes \Pi_2$ symmetry and the $SU(2) \times U(1)_Y$ gauge symmetry are

$$\mathcal{L}_{\text{Yuk}} \supset y_t \left( q \Phi_2 \bar{u} + q \Phi_1 \bar{U} \right) + \text{h.c.}$$

The model is not phenomenologically viable due to

- experimental limits on vector-like fermion masses
- existence of a massless scalar if the global $U(1)$ is spontaneously broken

Thus, we introduce $SU(2) \times U(1)_Y$ preserving mass terms,

$$\mathcal{L}_{\text{mass}} \supset M_U \bar{U}U + M_u \bar{u}U + \text{h.c.}$$

The $U(1)$ symmetry is explicitly broken if $M_U M_u \neq 0$. The $\Pi_2$ discrete symmetry is also explicitly broken if $M_U \neq M_u$. The symmetry breaking is soft, so that corrections to the scalar potential squared-mass parameters are protected from quadratic sensitivity to the cutoff scale $\Lambda$ of the theory.
Effects of the softly-broken symmetries

\[ \Delta m^2 \equiv m_{22}^2 - m_{11}^2 \sim \kappa (M_U^2 - M_u^2) - \frac{3y_t^2(M_U^2 - M_u^2)}{4\pi^2} \ln(\Lambda/M) , \]

where \( M \equiv (M_U^2 + M_u^2)^{1/2} \). The above result includes a finite threshold corrections proportional to \( \kappa \). Note that when \( M_U = M_u \), the \( \Pi_2 \) symmetry is unbroken and hence the relation \( m_{11}^2 = m_{22}^2 \) is protected. Likewise,

\[ m_{12}^2 \sim \kappa_{12} M_U M_u + \frac{3y_t^2 M_U M_u}{4\pi^2} \ln(\Lambda/M) , \]

which includes a finite threshold corrections proportional to \( \kappa_{12} \). In our numerical scans we chose \( \ln(\Lambda/M) = 3 \) and examined two benchmark points, \( \gamma = 0.1 \) and \( \gamma = 0.3 \), where \( \tan \gamma \equiv M_u/M_U \).
Regions of approximate alignment without decoupling

In addition to a SM-like Higgs boson (consistent with LHC data), we have also imposed:

- Non-SM Higgs bosons in the parameter regime of Higgs alignment without decoupling should have so far evaded LHC detection.

- Constraints on the charged Higgs mass from flavor constraints in the Type-I 2HDM.

- Vectorlike top quark mass bounds [we chose $M_T \gtrsim 1.5$ TeV].

- Constraints on mixing between the top quark and its vectorlike fermion partner (the mixing is governed by the parameters $\gamma, \beta, m_t$ and $M_T$).\(^7\)

- Avoid excessive fine-tuning while keeping small the size of the effects due to the soft breaking of the $U(1)\otimes\Pi_2$ symmetry.

Regions allowed by experimental bounds and tuning constraints for different values of $R \equiv (\lambda_3 + \lambda_4)/\lambda$, with an $m^2_{12}$ and $\Delta m^2$ tuning of at most 5% [assuming that $\ln(\Lambda/M) = 3$]. Each panel shows three different $R$ curves; the white regions of the parameter space are ruled out. The ruled out areas expand somewhat as $R$ decreases, with the borders of the allowed shaded regions indicated by the corresponding contours. For $R = -0.5$, the area enclosed by the closed dashed blue contour in panel (a) is also ruled out. Type-I Yukawa couplings are employed and, two choices for $\gamma$ are shown. Taken from P. Draper, A. Ekstedt and H.E. Haber, JHEP 05, 235 (2021) [arXiv:2011.13159 [hep-ph]].

Note: The shrinking of the allowed parameter space as $\gamma$ increases is due primarily to the behavior of the measure of fine-tuning of the parameter $m^2_{12}$. 
Take home Messages

- If an extended Higgs sector with additional “light” scalars exits, then one needs to understand why the observed Higgs boson is SM-like.

- Evidence for the additional Higgs scalars will first emerge either through their direct discovery or via the detection of deviations of the $h$ couplings from their SM predictions.

- In the case of the IDM, the deviations of the $h$ couplings from their SM predictions are radiatively induced and thus will be quite small.

- If additional Higgs scalars are found and deviations of $h$ from its SM behavior are confirmed (which are too large to be compatible with the IDM), then a symmetry-based explanation for why the Higgs boson is SM-like would suggest the presence of new physics in the Yukawa sector that involves top quark fermionic partners (and perhaps partners to other quarks and leptons).
Backup Slides
Extended Higgs Sectors are Highly Constrained

- The electroweak $\rho$ parameter is very close to 1.

- One neutral Higgs scalar of the extended Higgs sector must be SM-like (and identified with the Higgs boson at mass 125 GeV).

- At present, only one Higgs scalar has been discovered.

- Higgs-mediated flavor-changing neutral currents (FCNCs) are suppressed.

- Higgs-mediated CP-violation has not yet been observed (with implications for electric dipole moments).

- Charged Higgs exchange at tree level (e.g. in $\bar{B} \rightarrow D^{(*)} \tau^- \bar{\nu}_\tau$) and at one-loop (e.g. in $b \rightarrow s \gamma$) can significantly constrain the charged Higgs mass and the Yukawa couplings.
Motivations for Extended Higgs Sectors

- Extended Higgs sectors can modify the electroweak phase transition and facilitate baryogenesis.

- Extended Higgs sectors can enhance vacuum stability.

- Extended Higgs sectors can provide a dark matter candidate.

- Extended Higgs sectors can be employed to provide a solution to the strong CP problem (\(\Rightarrow\) axion)

- Models of new physics beyond the SM often require additional scalar Higgs states. E.g., two Higgs doublets are required in the minimal supersymmetric extension of the SM (MSSM).
A neutral scalar dark matter candidate—the inert doublet model (IDM)

The IDM is a 2HDM in which the scalar potential in a basis where \( \langle H_1 \rangle = v/\sqrt{2} \) and \( \langle H_2 \rangle = 0 \) exhibits an exact \( \mathbb{Z}_2 \) discrete symmetry.

All fields of the IDM—gauge bosons, fermions and the Higgs doublet field \( H_1 \) are even under \( \mathbb{Z}_2 \). Only the Higgs doublet field \( H_2 \) is \( \mathbb{Z}_2 \)-odd. Hence, there is no mixing between \( H_1 \) and \( H_2 \). In particular, the SM Higgs boson \( h \) resides in \( H_1 \). The lightest \( \mathbb{Z}_2 \)-odd particle (LOP) residing in \( H_2 \) is a candidate for the dark matter.

Note: deviations of \( h \) from SM Higgs properties can arise at one-loop (e.g., \( H^\pm \) loop corrections to \( h \to \gamma\gamma \)).
More family and GCP symmetries of the 2HDM

**Higgs family symmetries**

\[ \Pi_2' : \quad \Phi_1 \rightarrow \Phi_2, \quad \Phi_2 \rightarrow -\Phi_1 \]

\[ \text{U}(1)' : \quad \Phi_1 \rightarrow \Phi_1 c_\theta + \Phi_2 s_\theta \quad \Phi_2 \rightarrow -\Phi_1 s_\theta + \Phi_2 c_\theta \]

\[ \text{U}(1)'' : \quad \Phi_1 \rightarrow \Phi_1 c_\theta + i\Phi_2 s_\theta \quad \Phi_2 \rightarrow i\Phi_1 s_\theta + \Phi_2 c_\theta \]

Part I of the classification of symmetries of the 2HDM scalar potential that yield exact Higgs alignment. Note that $m_{11}^2 = m_{22}^2$ and $\text{Re}(m_{12}^2 e^{i\xi}) = \text{Im}(m_{12}^2 e^{i\xi}) = 0$ unless otherwise indicated. In cases where the vacuum preserves a $\text{U}(1)$ symmetry, $m_H = m_A \neq 0$. Since GCP3 is equivalent to $\text{U}(1) \otimes \Pi_2$ when expressed in a different scalar field basis, there is a one-to-one mapping between the corresponding entries in this Table and the one that follows. Taken from H.E. Haber and J.P. Silva, Phys. Rev. D 103, 115012 (2021).

Part II of the classification of symmetries of the 2HDM scalar potential that yield exact Higgs alignment. Note that $m_{11}^{'2} = m_{22}^{'2}$ and $Re (m_{12}^{'2} e^{i\xi'}) = Im (m_{12}^{'2} e^{i\xi'}) = 0$ unless otherwise indicated, where the primed parameters correspond to the GCP3 scalar field basis. The symmetry group $U(1)_H$ refers to a Peccei-Quinn $U(1)$ symmetry that is manifestly realized in the Higgs basis. In cases where the vacuum preserves a $U(1)$ symmetry, $m_H = m_A \neq 0$ (with the exception of the unbroken SO(3)-symmetric scalar potential where both $H$ and $A$ are massless). Taken from H.E. Haber and J.P. Silva, Phys. Rev. D 103, 115012 (2021).
