

The HL-LHC: Strategies for beam optics commissioning

Wednesday, July 29, 2020 3:30 PM (20 minutes)

Beam optics control in the HL-LHC will present significant challenges, relating to the extremely low- β^* in the two main experiments: ATLAS and CMS. The luminosity delivered to the experiments during the first several hours of HL-LHC fills will be kept constant via β^* -levelling. Such an extensive optimisation will require the commissioning of a large number of optical configurations, further challenging the efficiency of the beam optics measurement and correction methods. Throughout the LHC's run 2, beam-based studies have helped identify critical challenges and their solutions. Based on the experience and the achieved level of optics control, we discuss strategies of HL-LHC optics commissioning and its implications for the experiments.
