Sub-GeV dark matter model: $U(1)_{T3R}$ extension of SM

Tuesday, 24 August 2021 20:20 (20 minutes)

Scenarios in which right-handed light Standard Model fermions couple to a new gauge group, $U(1)_{T3R}$ can naturally generate a sub-GeV dark matter candidate. But such models necessarily have large couplings to the Standard Model, generally yielding tight experimental constraints.

We show that the contributions to $g_\mu - 2$ from the dark photon and dark Higgs largely cancel out in the narrow window where all the experimental constraints are satisfied, leaving a net correction which is consistent with recent measurements from Fermilab.

These models inherently violate lepton universality, and UV completions of these models can include quark flavor violation which can explain $R_{K^{(*)}}$ anomalies as observed at the LHCb experiment after satisfying constraints on $Br(B_s \rightarrow \mu^+ \mu^-)$ and various other constraints in the allowed parameter space of the model. This scenario can be probed by FASER, SeaQuest, SHiP, LHCb, Belle, etc.
