The Race to Find Split Higgsino Dark Matter

Tuesday, 24 August 2021 10:55 (20 minutes)

Higgsinos are a particularly compelling form of dark matter, and are on the verge of detection by multiple current experimental avenues. They can arise in models with decoupled scalars that enjoy the benefits of depending on very few parameters while still explaining gauge coupling unification, dark matter, and most of the hierarchy between the Planck and electroweak scales, and they remain undetected to past experiments. My talk will cover the reach for current and upcoming electron electric dipole moment experiments as compared to direct and indirect detection as avenues to observe higgsino dark matter models.
