5 Summary

- We can only (severely) constrain $T \lesssim 10$ MeV. There is the possibility that cosmic history is different than what we assume.

- We can only (severely) constrain $T \lesssim 10$ MeV. There is the possibility that cosmic history is different than what we assume.
- Theoretical motivation: SUSY, string theory, and other models.

- We can only (severely) constrain $T \lesssim 10$ MeV. There is the possibility that cosmic history is different than what we assume.
- Theoretical motivation: SUSY, string theory, and other models.
- DM may open a window to the cosmic evolution at higher temperatures.

5 Summary

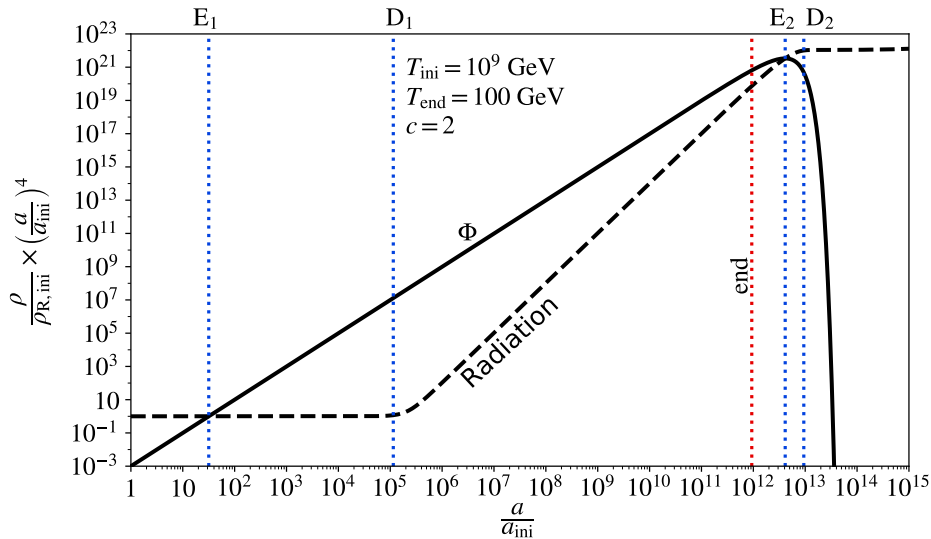

Cosmological components: equations

Assume that there is a fluid (Φ), which at some point dominates the energy density of the Universe, and later deposits energy to plasma with rate Γ_Φ . The equation of state of Φ is $p_\Phi = 1/3 (c - 3) \rho_\Phi$ (critical assumption: $c = \text{const.}$)

$$\frac{d\rho_\Phi}{dt} = -cH \rho_\Phi - \Gamma_\Phi \rho_\Phi$$
$$\frac{ds}{dt} = -3H s + \frac{\Gamma_\Phi}{T} \rho_\Phi$$

The temperature at which Φ decays away in a radiation dominated (RD) Universe (T_{end}) can be calculated by $\Gamma_\Phi = H_{\text{R}}(T_{\text{end}})$. It is more convenient to use this temperature as a free parameter instead of Γ_Φ .

5 Summary

Dark matter production: qualitative description

The Dark Matter particle (χ) is produced via

$$\mathcal{L}_{\text{int}} = -\frac{y_\chi}{2} S (\chi\chi + \chi^\dagger\chi^\dagger) ,$$

with S being in equilibrium with the plasma. ¹

The BE in terms of the DM yield, $Y_\chi \equiv n_\chi/s$, is expressed as

$$\frac{d \log Y_\chi}{d \log \frac{T_{\text{ini}}}{T}} = \delta_h \frac{\{S \rightarrow \chi\chi\} + \{SS \rightarrow \chi\chi\}}{H_{\text{R}} n_\chi} \times$$
$$\underbrace{\frac{H_{\text{R}}}{H}}_{0 < \mathcal{F}_1 \leq 1} \underbrace{\left(1 - \frac{\Gamma_\Phi}{H} \frac{\rho_\Phi}{3sT}\right)^{-1}}_{1 \leq \mathcal{F}_2 \lesssim 8/c} \underbrace{\left[1 - \frac{d \log S}{d \log \frac{T_{\text{ini}}}{T}} \left(\frac{d \log N_\chi}{d \log \frac{T_{\text{ini}}}{T}}\right)^{-1}\right]}_{\mathcal{F}_3 \leq 1} .$$

¹ There is an extensive discussion on freeze-in production in NSCs, such as . J. H. Chung, E. W. Kolb and A. Riotto, *Phys. Rev. D* **60** (1999) 063504[hep-ph/9809453], M. Drees and F. Hajkarim, *JCAP* **1802**, 057 (2018) [arXiv:1711.05007], F. D'Eramo, N. Fernandez and S. Profumo, *JCAP* **1802**, 046 (2018) [arXiv:1712.07453], N. Bernal, F. Elahi, C. Maldonado and J. Unwin, [arXiv:1909.07992], and many others.

Dark matter production: example

- Φ significantly alters the DM production.
- If $T_{\text{FI}} < T_{D_2}$, the final result is the same as in RD (consequence of infrared freeze-in).
- The maximum relic is obtained for RD, despite $\mathcal{F}_{1,2}$.
- The change of the sign of \mathcal{F}_3 causes minima and maxima, which affect DM thermalization.

Dark matter momentum: qualitative description

Matching today's DM momentum with the WDM scenario,² DM mass has to obey

$$m_\chi > \frac{\langle p_{\chi,0} \rangle}{1.2 \times 10^{-7}} \left(\frac{m_{\text{WDM}}}{\text{keV}} \right)^{4/3}.$$

Generally one has to solve the Boltzmann equation for the phase-space distribution of χ .³ However, assuming that the distribution of S is sharp (*i.e.* the variance of the energy of S is small), we derive an equation for the DM mean momentum. For $T > T_{\text{EW}} \sim 150$ GeV and $m_\chi \ll T$, this equation can be written as

$$\frac{d \log \frac{\langle p_\chi \rangle}{T}}{d \log \frac{T_{\text{ini}}}{T}} = \underbrace{1 - \left(1 - \frac{\Gamma_\Phi}{H} \frac{\rho_\Phi}{3s T} \right)^{-1}}_{1 - \frac{8}{c} \lesssim \mathcal{T}_1 \leq 0} + \overbrace{\left(\frac{1}{2} \frac{\langle E_S \rangle}{T} \frac{T}{\langle p_\chi \rangle} - 1 \right)}^{\mathcal{T}_2 \geq 0} \frac{d \log N_\chi}{d \log \frac{T_{\text{ini}}}{T}}.$$

² Similarly to R. Huo, *Phys. Lett. B* **802** (2020), 135251 [arXiv:1907.02454].

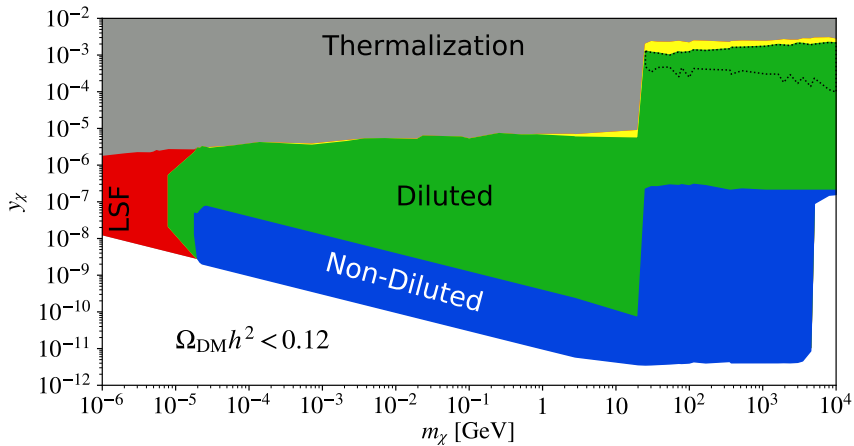

³ Also see [Alessandro's presentation](#).

Dark matter momentum: example

- Φ changes the evolution of DM momentum.
- If $T_{\text{FI}} < T_{D_2}$, the final result is the same as in RD.
- For $T_{\text{FI}} > T_{D_2}$, $\langle p_{\chi} \rangle$ redshifts faster than T .
- If $T_{\text{FI}} \approx T_{D_2}$, $\langle p_{\chi} \rangle$ is slightly enhanced.

5 Summary

Axion DM production: misalignment mechanism

The (zero-mode) axion equation of motion is

$$\frac{d^2\theta}{du^2} + \left[\frac{1}{2} \frac{d \log H^2}{du} + 3 \right] \frac{d\theta}{du} + \left(\frac{\tilde{m}_a}{H} \right)^2 \sin \theta = 0 ,$$

with \tilde{m}_a the temperature-dependent axion mass, and $u = \log \frac{R}{R_{\text{ini}}}$.

- Oscillation temperature, T_{osc} , at $\tilde{m}_a = 3H$.
- For $T \gg T_{\text{osc}}$, $\theta \approx \theta_{\text{ini}} = \text{const}$.
- For $T \approx T_{\text{osc}}$, time-dependent pendulum with time-dependent friction.
- For $T \ll T_{\text{osc}}$, adiabatic evolution.

Assuming entropy is increased by γ (after adiabatic evolution starts), the WKB estimate is

$$\rho_{a,0} = \gamma^{-1} \frac{s_0}{s_{\text{osc}}} \frac{1}{2} f_a^2 m_a \tilde{m}_{a,\text{osc}} \theta_{\text{ini}}^2 ,$$

5 Summary

What we did:

- Detailed treatment of freeze-in in NSC scenarios.
- Detailed analysis of axion DM in NSC scenarios.

What we saw:

- Possibility for larger couplings without over-closing the Universe, with interesting DM momentum behaviour.
- Distinct “natural” axion window that depends on the type of NSC, *i.e.* depending on whether $c > 4$ or $c < 4$.

What we want to see:

- Potential detection of FIMPs?
- Detection of axions can exclude or probe NSC scenarios?

Thank you!
