

Parton showers beyond leading logarithmic accuracy

Taming the accuracy of event generators, CERN, 29 June 2020

Frédéric Dreyer

Core questions on event generators

- ▶ Why is improving event generators important for precision measurements at the LHC?
- ▶ What decisions and physics go into designing a parton shower?
- ▶ How do we assess the accuracy of a parton shower?
- ▶ Can we systematically achieve next-to-leading logarithmic accuracy for broad range of observables?

Why are event generators important?

- ▶ Provide realistic and generic all-purpose simulations used in broad range of analyses with various cuts and observable choices.
- ▶ LHC collisions probe wide range of scales at which physics needs to be described accurately.
- ▶ Event generators are relied on for many different purposes, e.g.
 - ▶ background and signal estimates for new physics searches
 - ▶ uncertainty estimates for standard model measurements
 - ▶ phenomenology studies of new tools and observables
 - ▶ training data for machine learning models

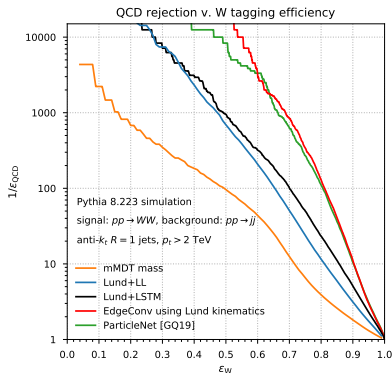

What goes into simulating a high-energy collision?

- ▶ LHC collisions probe physics across scales, from hard process at the TeV scale to non-perturbative modelling below the GeV scale.
- ▶ Parton showers span several orders of magnitude to provide crucial link between hard interaction and observable particles.
- ▶ Multi-scale evolution lead to large logarithms of ratio of scales: to what accuracy are they under control?

What information is hidden in an event?

- ▶ There has been much progress in using jet substructure to design efficient taggers for boosted $H/W/Z$ bosons.
- ▶ Recent state-of-the-art tools use machine learning models trained on Monte Carlo data.
- ▶ These methods are only as good as the training data they rely on.

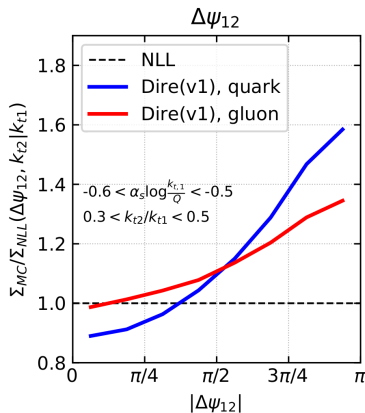

Azimuthal structure in jets

- ▶ Consider the angle $\Delta\psi_{12}$ between the hardest emissions in a jet.

Azimuthal structure in jets

- ▶ Consider the angle $\Delta\psi_{12}$ between the hardest emissions in a jet.
- ▶ Large deviations from NLL in current dipole showers.
- ▶ Difference between quark and gluon distributions might lead to models that learn to discriminate based on a feature that **doesn't exist in real data!**

Basic picture of dipole showers

- ▶ Many showers are dipole/antenna showers where gluon emissions correspond to dipole splittings.
- ▶ Squared amplitudes obtained from recursive chain of emissions.

Two key ingredients:

- ▶ kinematic mapping $\tilde{p}_i, \tilde{p}_j \rightarrow p_i, p_j, p_k$.
- ▶ evolution variable v defining order of emissions.

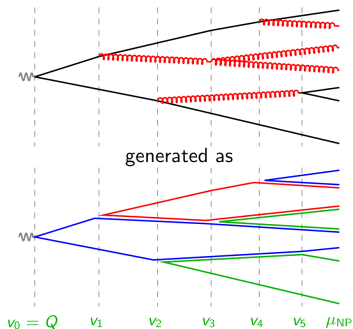

Dipole shower evolution

Evolution from state with n particles to state with $n + 1$ is described by

$$\frac{d\mathcal{P}_{n \rightarrow n+1}}{d \ln v} = \sum_{\text{dipoles } \{\tilde{i}, \tilde{j}\}} \int d\bar{\eta} \frac{d\phi}{2\pi} \frac{\alpha_s(k_t) + K\alpha_s^2(k_t)}{\pi} \times \left[g(\bar{\eta}) a_k P_{\tilde{i} \rightarrow ik}(a_k) + g(-\bar{\eta}) b_k P_{\tilde{j} \rightarrow jk}(b_k) \right],$$

- ▶ v is the evolution variable (e.g. k_t in dipole c.o.m. frame)
- ▶ $g(\bar{\eta})$ is a function partitioning the dipole using the rapidity of the emission within the dipole (with $g(\bar{\eta}) + g(-\bar{\eta}) = 1$)
- ▶ $P_{\tilde{i} \rightarrow ik}(z)$ are first-order splitting functions

What is the accuracy of a parton shower?

- ▶ Parton showers are often referred to as leading logarithmic accurate.
- ▶ This means that it generates the correct squared amplitude in limit where both energy and angle of emissions are strongly ordered.
- ▶ Distributions can be compared to analytic resummations

For example, Thrust, defined as

$$T = \max_{\vec{n}_T} \frac{\sum_i |\vec{p}_i \cdot \vec{n}_T|}{\sum_i |\vec{p}_i|}$$

we have, for $\alpha_s L \sim 1$

$$\sigma(1 - T < e^{-L}) = \sigma_0 \exp \left[\underbrace{L g_1(\alpha_s L)}_{\text{LL}} + \underbrace{g_2(\alpha_s L)}_{\text{NLL}} + \underbrace{\alpha_s g_3(\alpha_s L)}_{\text{NNLL}} + \dots \right]$$

What is the accuracy of a parton shower?

- ▶ Are existing dipole showers strictly LL accurate for all observables or better in some contexts?
- ▶ For what observables do we achieve a given accuracy with a given parton shower?
- ▶ Can we design a parton shower that can systematically achieve NLL accuracy for broad range of observables?
 - ▶ global event shapes (Thrust, jet rates, angularities, broadening, ...)
 - ▶ non-global observables (e.g. energy in a rapidity slice)
 - ▶ multiplicity

Achieving NLL accuracy

- ▶ NLL accuracy requires that the shower generates correct squared amplitude in a limit where every pair of emissions is strongly ordered for at least one logarithmic variable k_t and θ .
- ▶ I.e., should reproduce correct effective matrix element squared when all emissions are well separated in Lund diagram ($d_{12}, d_{23}, \dots \gg 1$)

Achieving NLL accuracy

- ▶ NLL accuracy requires that the shower generates correct squared amplitude in a limit where every pair of emissions is strongly ordered for at least one logarithmic variable k_t and θ .
- ▶ I.e., should reproduce correct effective matrix element squared when all emissions are well separated in Lund diagram ($d_{12}, d_{23}, \dots \gg 1$)
- ▶ allowed to make $O(1)$ mistake when pair of emissions is close ($d_{23} \sim 1$)

Ingredients of a shower

There are two key ingredients in the design of a parton shower

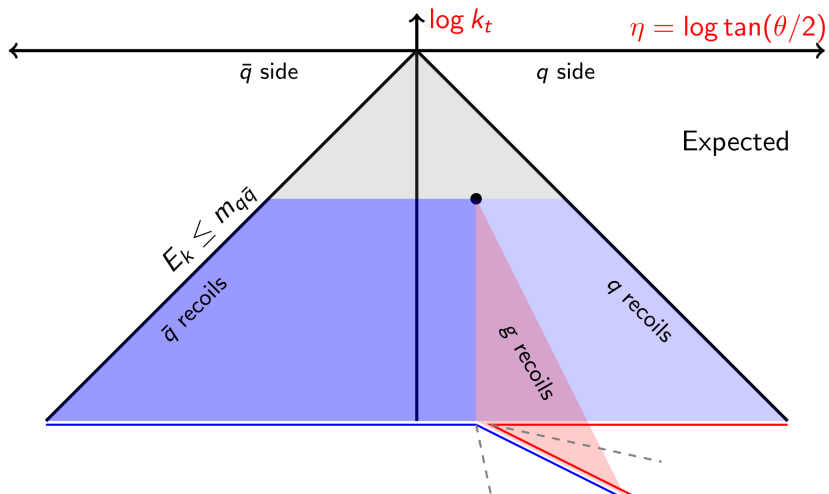

- ▶ How to associate colour and transverse recoil to dipoles?

- ▶ The choice of evolution variable (transverse momentum, angle, ...)

Design two new showers with different recoil: PanLocal and PanGlobal

Transverse recoil boundaries

Transverse recoil boundaries

- ▶ transverse recoil assigned to end that is closer in angle in dipole c.o.m. frame

Transverse recoil boundaries

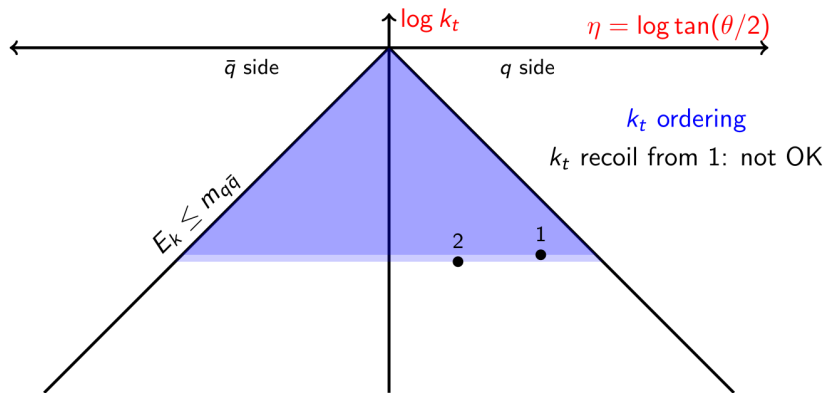

- ▶ transverse recoil assigned to end that is closer in angle in **event** c.o.m. frame

Choice of ordering variable

Choice of ordering variable

Choice of ordering variable

- ▶ Use ordering variable intermediate between transverse momentum and angle $0 < \beta < 1$.
- ▶ Ensures that emissions with commensurate k_t are produced at successively smaller angles.

Kinematic map of the PanLocal shower

dipole $\tilde{p}_i, \tilde{p}_j \implies p_i, p_j, p_k$.

$$\begin{aligned} p_k &= a_k \tilde{p}_i + b_k \tilde{p}_j + k_\perp, & k_t &= \rho v e^{\beta|\bar{\eta}|}, & \rho &= \left(\frac{s_{\tilde{i}\tilde{j}} s_{\tilde{j}}}{Q^2 s_{\tilde{i}\tilde{j}}} \right)^{\frac{\beta}{2}}. \\ p_i &= a_i \tilde{p}_i + b_i \tilde{p}_j - f k_\perp, & a_k &\equiv \sqrt{\frac{s_{\tilde{j}}}{s_{\tilde{i}\tilde{j}} s_{\tilde{i}}}} k_t e^{+\bar{\eta}}, & b_k &\equiv \sqrt{\frac{s_{\tilde{i}}}{s_{\tilde{i}\tilde{j}} s_{\tilde{j}}}} k_t e^{-\bar{\eta}}, \\ p_j &= a_j \tilde{p}_i + b_j \tilde{p}_j - (1-f) k_\perp, \end{aligned}$$

where $f \rightarrow 1$ for $k \rightarrow i$ and $f \rightarrow 0$ for $k \rightarrow j$.

where $s_{\tilde{i}\tilde{j}} = 2\tilde{p}_i \cdot \tilde{p}_j$, $s_{\tilde{i}} = 2\tilde{p}_i \cdot Q$

Partitioning of the dipole occurs at equal angles between the emission and the dipole ends in the event c.o.m. frame

Alternative scheme: global recoil

Alternatively, we can formulate a global recoil scheme, which defines the **PanGlobal** shower.

Longitudinal recoil is handled by dipole-local map

$$\text{dipole } \{\tilde{p}_i, \tilde{p}_j\} \implies \begin{aligned} \bar{p}_k &= a_k \tilde{p}_i + b_k \tilde{p}_j + k_\perp, \\ \bar{p}_i &= (1 - a_i) \tilde{p}_i, \\ \bar{p}_j &= (1 - b_k) \tilde{p}_j. \end{aligned}$$

But transverse recoil is distributed across whole event by boost and rescaling.

- ▶ This scheme works for $0 \leq \beta < 1$, i.e. including for k_t ordering.

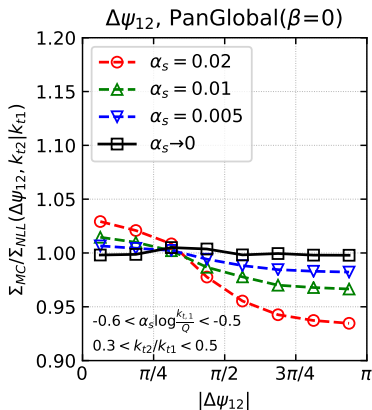

How to probe the accuracy of a shower

- ▶ Run full shower for smaller and smaller values of α_s , keeping $\alpha_s L$ constant
- ▶ Ratio to NLL of each distribution deviates from one: because of residual NNLL term or because of NLL mistake?

How to probe the accuracy of a shower

- ▶ Run full shower for smaller and smaller values of α_s , keeping $\alpha_s L$ constant
- ▶ Ratio to NLL of each distribution deviates from one: because of residual NNLL term or because of NLL mistake?
- ▶ Extrapolation $\alpha_s \rightarrow 0$ proves agreement with NLL, here for $\Delta\psi_{12}$ observable considered earlier

How to probe the accuracy of a shower

- ▶ Run full shower for smaller and smaller values of α_s , keeping $\alpha_s L$ constant
- ▶ Ratio to NLL of each distribution deviates from one: because of residual NNLL term or because of NLL mistake?
- ▶ Extrapolation $\alpha_s \rightarrow 0$ proves agreement with NLL, here for $\Delta\psi_{12}$ observable considered earlier

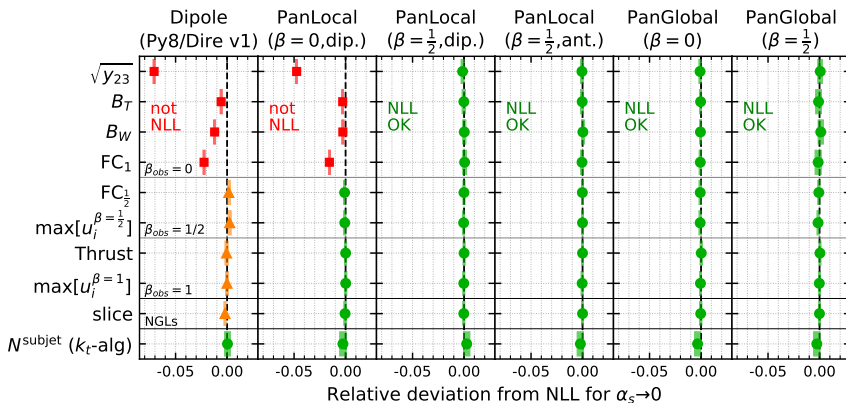

What tests should a NLL shower pass?

NLL accurate shower should pass numerical tests showing agreement with analytic NLL resummation for broad range of observables:

- ▶ event shapes sensitive to transverse momentum, e.g. jet broadenings
- ▶ event shapes probing $k_t e^{-|\eta|/2}$, e.g. fractional moment $FC_{1/2}$
- ▶ event shapes probing $k_t e^{-|\eta|}$, e.g. thrust
- ▶ non-global observables e.g. transverse momentum in a rapidity slice
- ▶ jet multiplicity probing the recursive structure of the shower

Systematic assessment of parton shower accuracy

- Pythia 8 deviates from NLL, while PanLocal $0 < \beta < 1$ and PanGlobal $0 \leq \beta < 1$ correctly reproduces global observables, non-global observables and multiplicities.

Orange coding indicates NLL issues at fixed order that are masked at all orders.

CONCLUSIONS

- ▶ Parton showers and their accuracies is an essential component for the theoretical and experimental HEP program.
- ▶ Formal accuracy of a shower can be defined in terms of comparison with analytic resummations, using systematic numerical checks.
- ▶ From simple building blocks, possible to design shower that is NLL accurate, i.e. controlling terms $O(\alpha_s^n L^n)$, for both global and non-global observables.
- ▶ Paves the way for further progress: subleading colour, spin correlations, ISR, NNLL, ...
