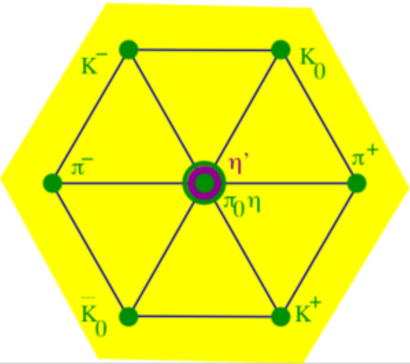
Outline

1. Overview of η and η' physics
2. Two experiments in Hall D at JLab
   - PrimEx-eta experiment
   - JLab Eta Factory (JEF) experiment
3. Summary

Why η is a unique probe for QCD and BSM physics?

- A Goldstone boson due to spontaneous breaking of chiral symmetry in QCD
  → η plays important role in bridging our understanding of low-energy hadron dynamics and underlying QCD



- All its possible strong and EM decays are forbidden in the lowest order so that η has narrow decay width (Γ_η =1.3KeV compared to Γ_ω=8.5 MeV)
  → Enhanced sensitivity to the higher order contributions (by a factor of ~7000 compared to ω decays) for new physics search

- Eigenstate of P, C, CP, and G: $I^G J^{PC} = 0^+ 0^{-+}$
  → tests for C, CP

- All its additive quantum numbers are zero and its decays are flavor-conserving
  → effectively "free" of SM backgrounds for new physics search.

Precision Determination Light Quark Mass Ratio

A clean probe for quark mass ratio: $Q^2 = \frac{m_s^2 - \hat{m}^2}{m_d^2 - m_u^2}$, where $\hat{m} = \frac{1}{2}(m_u + m_d)$

- $\eta \to 3\pi$ decays through isospin violation: $A = (m_u - m_d)A_1 + \alpha_{em}A_2$
- α_{em} is small
- Amplitude: $A(\eta \to 3\pi) = \frac{1}{Q^2}\frac{m_K^2}{m_\pi^2}(m_\pi^2 - m_K^2)\frac{M(s,t,u)}{3\sqrt{3}F_\pi^2}$

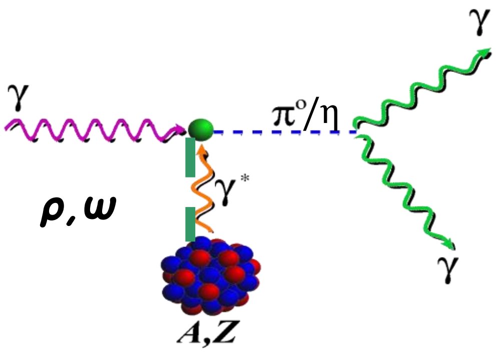
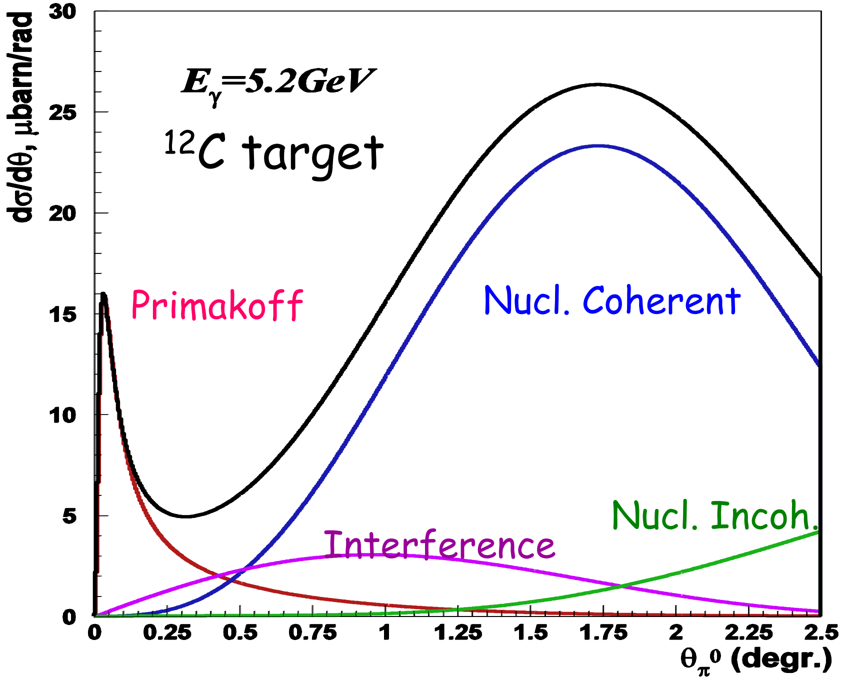
- Critical input to extract Cabibbo Angle, $V_{us} = \sin(\theta_c)$ from kaon or hyperon decays.
- V_{us} is a cornerstone for test of CKM unitarity: $|V_{ud}|^2 + |V_{us}|^2 + |V_{ub}|^2 = 1$

Primakoff Method



$$\frac{d\sigma_{\rm Pr}}{d\Omega} = \Gamma_{\gamma\gamma} \frac{8\alpha Z^2}{m_\pi^3} \frac{\beta^3 E^4}{Q^4} |F_{e.m.}(Q)|^2 \sin^2\theta_\pi$$



Requirement:

- Photon flux
- Beam energy
- Compact nuclear target

← Tagged photon beam

- Peaked at very small forward angle

$$\langle\theta_{\rm Pr}\rangle_{peak} \propto \frac{m^2}{2E^2}$$

- Beam energy sensitive:

$$\left\langle\frac{d\sigma_{\rm Pr}}{d\Omega}\right\rangle_{peak} \propto E^4, \quad \int d\sigma_{\rm Pr} \propto Z^2 \log(E)$$

- Coherent process

Experimental Challenges

Compared to π^0:

- η mass is a factor of 4 larger
- smaller Primakoff cross section

$$\left\langle \frac{ds_{\mathrm{Pr}}}{dW} \right\rangle_{peak} \mu \; \frac{E^4}{m^3}$$

- larger overlap between Primakoff and hadronic processes;

$$\langle q_{\mathrm{Pr}} \rangle_{peak} \mu \; \frac{m^2}{2E^2} \qquad \langle q_{NC} \rangle_{peak} \mu \; \frac{2}{E \cdot A^{1/3}}$$

- larger momentum transfer (coherency, form factors, FSI,…)

1. Higher beam energy
2. Light targets

Advantage of Light Targets

Low A targets to control:

- Coherency: compact nucleus

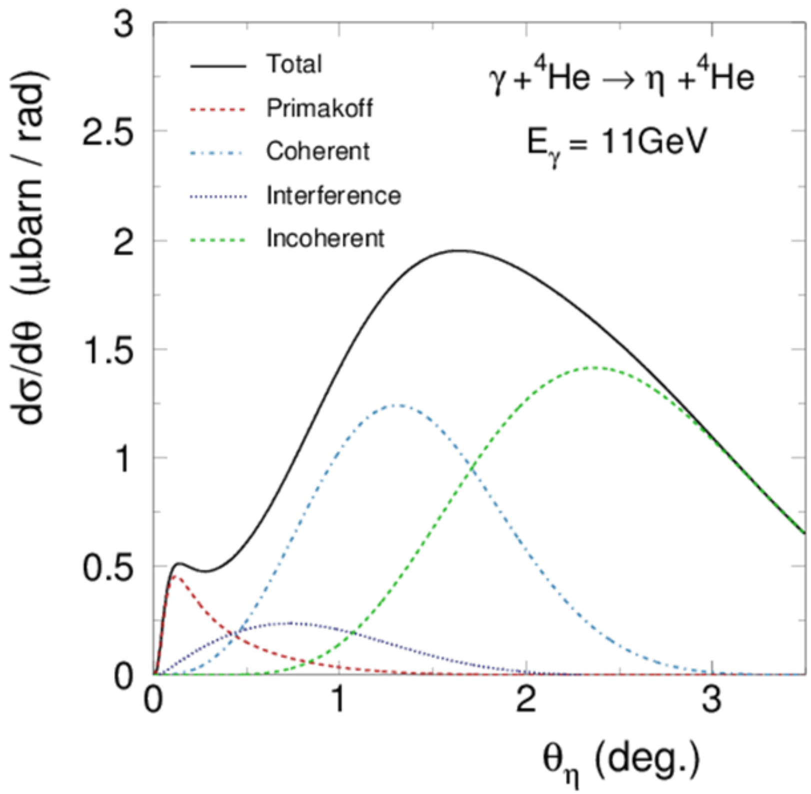
$$\langle q_{\mathrm{Pr}} \rangle_{peak} \ \mu \ \frac{m^2}{2E^2} \qquad \langle q_{NC} \rangle_{peak} \ \mu \ \frac{2}{E \cdot A^{1/3}}$$

- Well known form factors



Hydrogen:

- No inelastic hadronic contribution
- No nuclear final state interactions

^{4}He:

- Higher Primakoff cross section: $\sigma_{\mathrm{Pr}} \propto Z^2$
