

# Helium as a range probe in carbon ion therapy

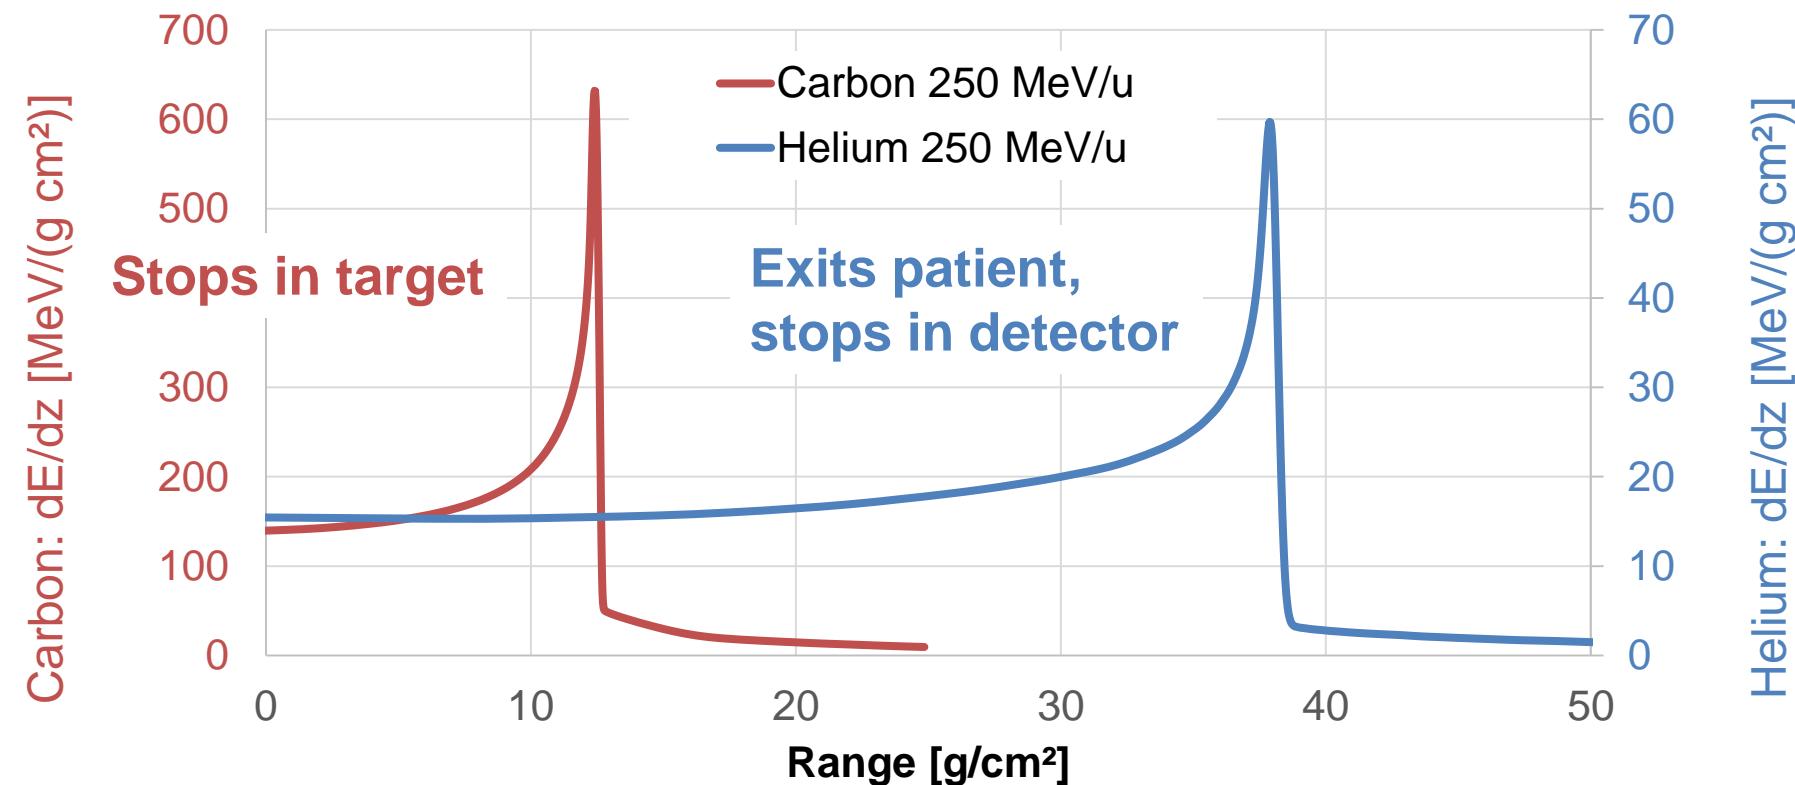

C. Graeff, J. Seco, N. Saito et al

## Range uncertainty - a major issue

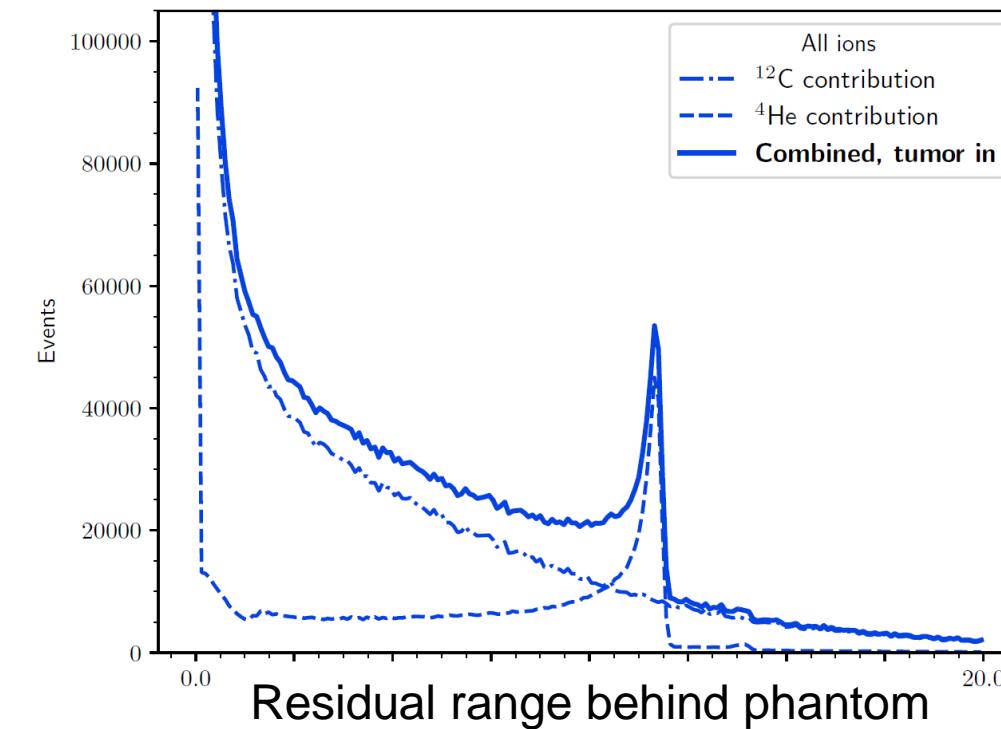

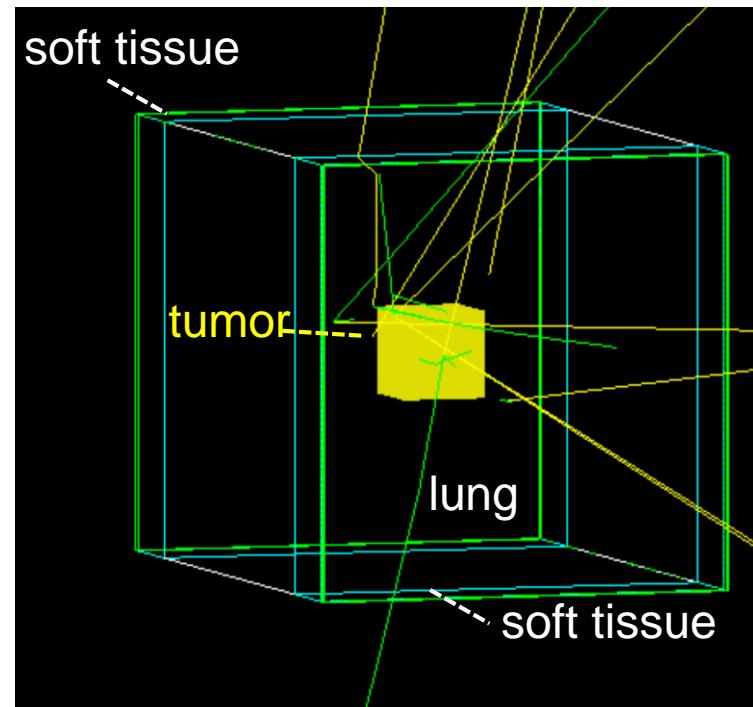

## A mixed He-C beam

- Fully ionized Helium and Carbon – (nearly) same mass:charge ratio
- Can be accelerated to same velocity - range of  ${}^4\text{He}^{2+} \approx 3 \times$  range of  ${}^{12}\text{C}^{6+}$

# Monte Carlo: Carbon fragments vs. primary Helium

- Simple test setup: parallel plates of soft tissue, lung, and tumor
- Residual range of all particles exiting distal phantom plane recorded

- Helium can be separated from Carbon fragment tail

## Feasibility test: a patient simulation

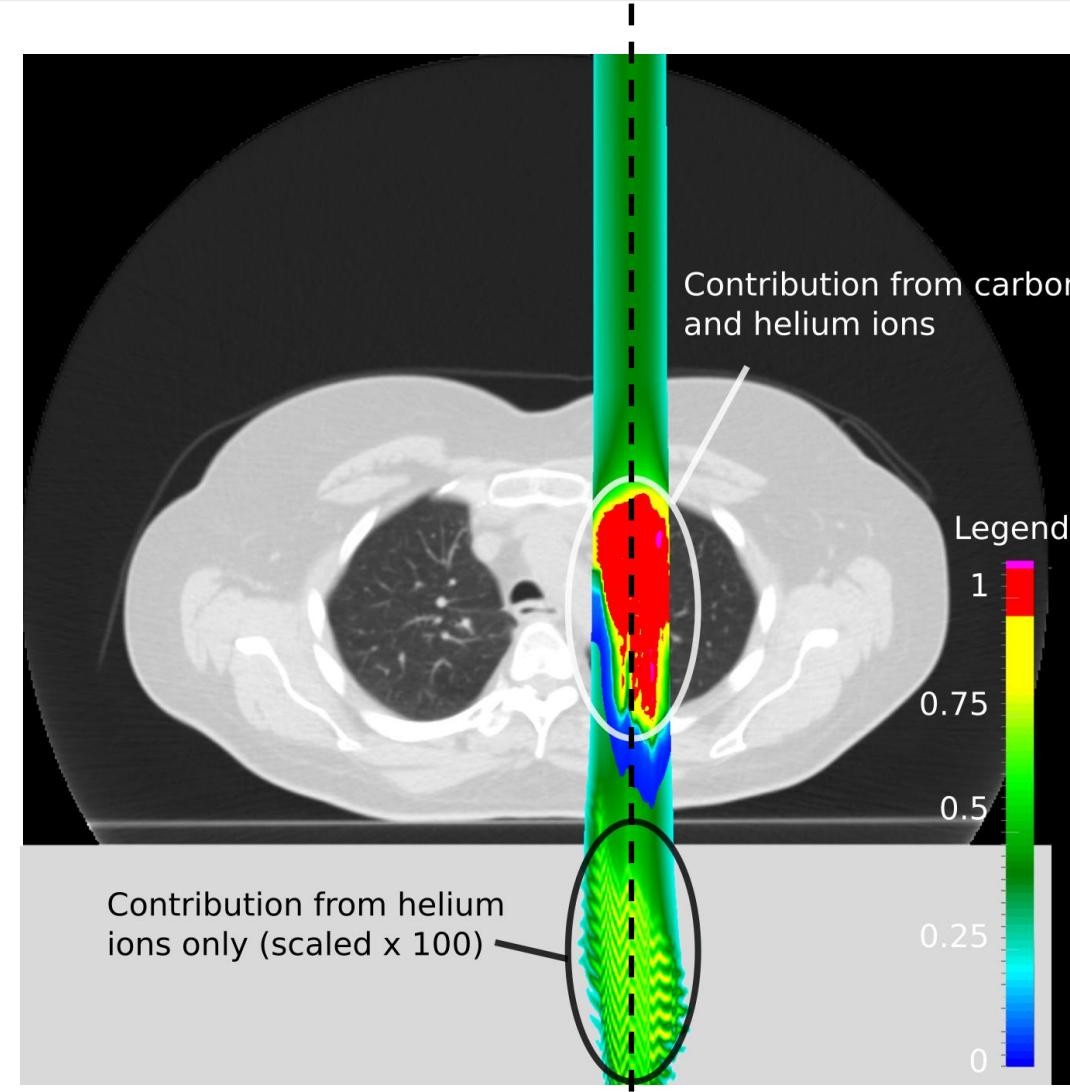

- RBE-weighted doses & optimization of mixed beam using LEM IV
- Plan setup & optimization steered by carbon therapy
  - Helium dose considered
  - ... but assigned fixed portion of spot weight  $N$  in each iteration  $i$

$$D_{RBE} = (D_{absorbed}^{He} + D_{absorbed}^C) \cdot RBE_{He,C}$$

$$N_{i+1,He} = \rho \cdot N_{i,C}$$

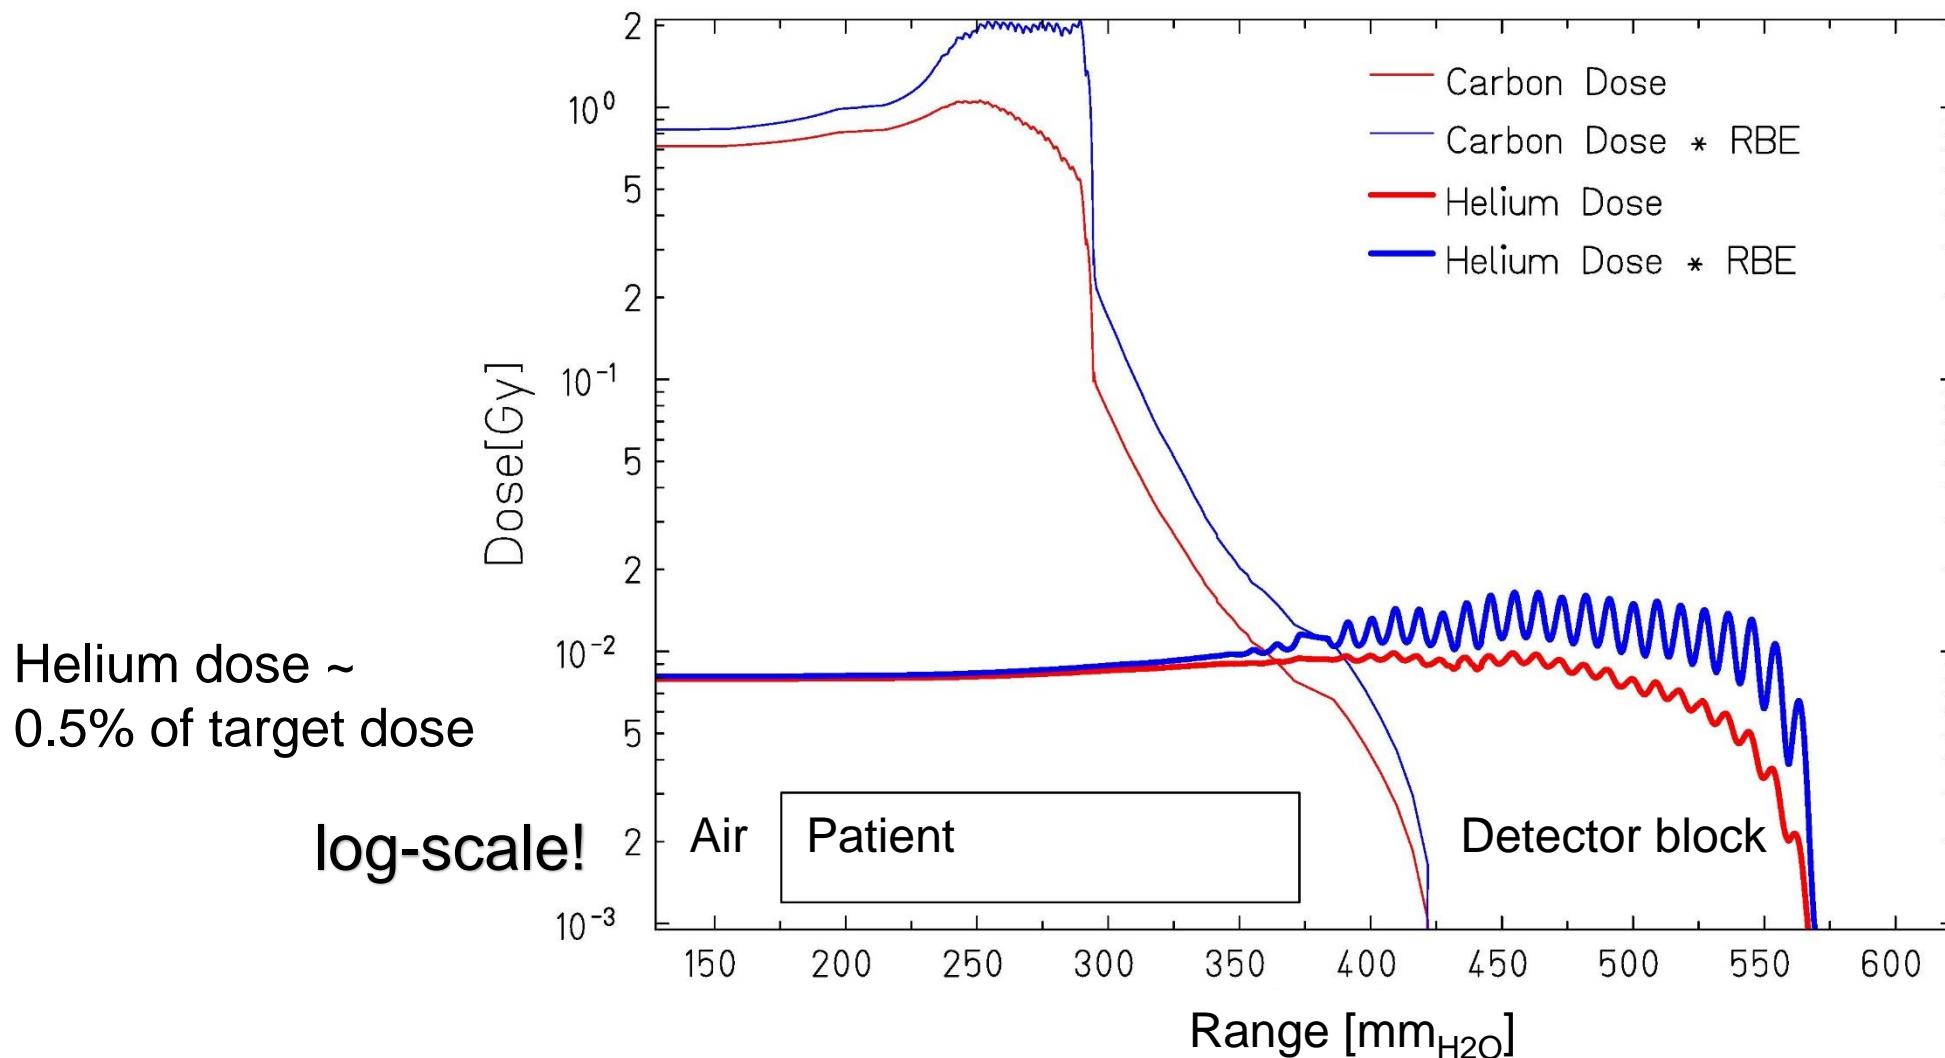

- Single AP field: 2 Gy(RBE), no OARs considered,  $\rho = 10\%$

# Image-guided particle therapy

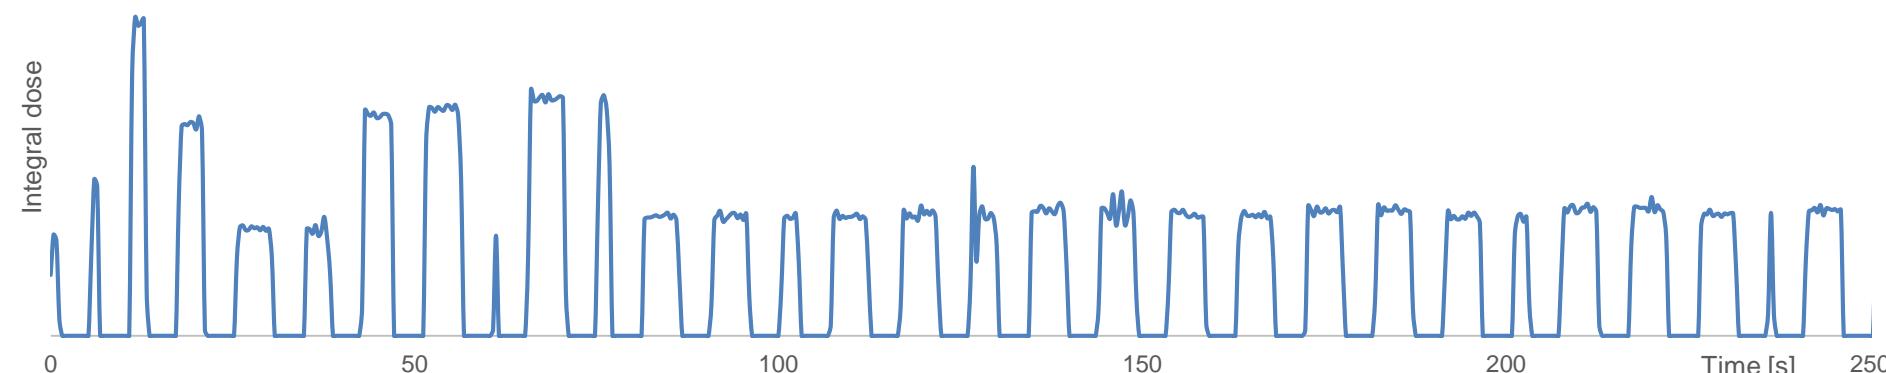

Beam' eye view  
dose profile  
(next slide)

# Dose profile along central beam axis

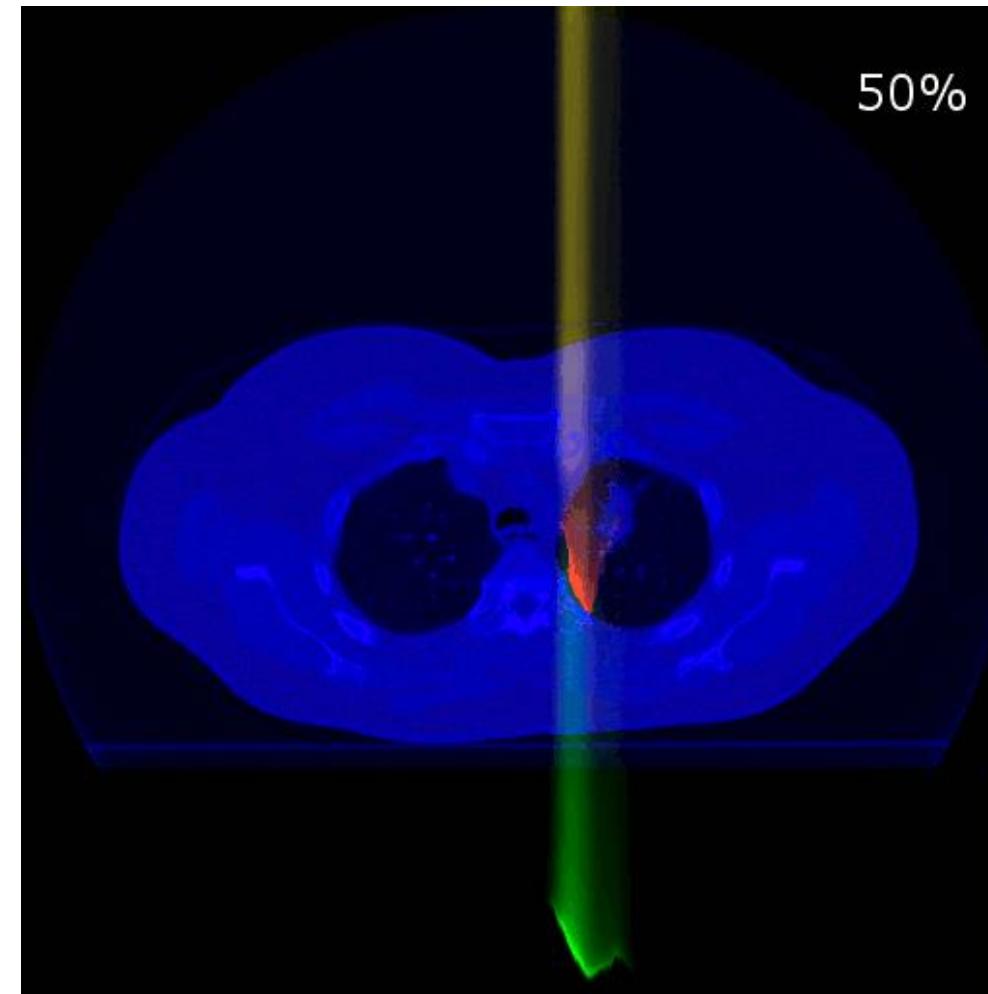

# Preliminary: Range detection under motion

- Time-resolved simulation of same plan as for static test
- Dose calculated for each motion phase of 400 ms
  - Plan simulated for GSI Cave M: 26 IES in 56 spills
  - single breathing trajectory with 4 sec period
  - Dose calculated for each consecutive motion phase
- Mimicking an IC / scintillator stack:  
Dose integrated on each CT plane perpendicular to the beam
- Quantification of range ongoing –  
qualitative impression for consecutive motion phases, single energy

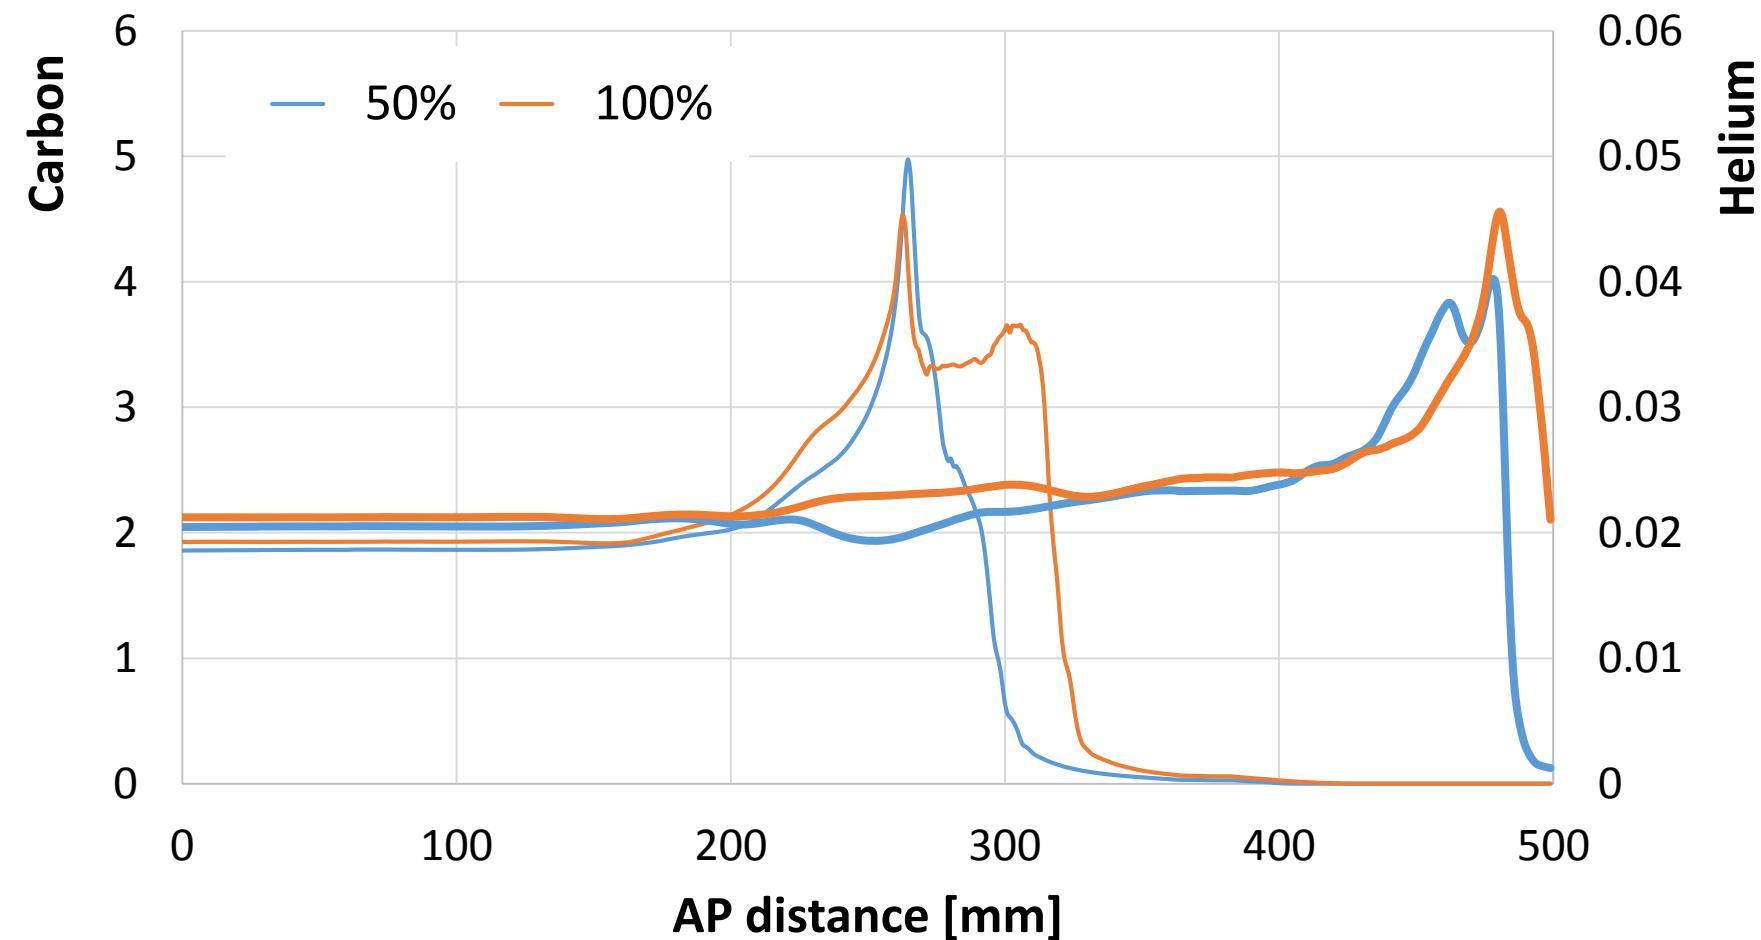

# Preliminary: Range detection under motion

Carbon  
Helium

Motion phases #555 to #550; E = 210.83 MeV/u

# Integral dose perpendicular to beam

## Outlook

- Simulations show feasibility for **online portal imaging and range detection** at low additional dose (<0.5% at 10 % He)
- Clinical relevance: Identify suitable patients
  - Carbon range to tumor sets energy, Helium not always exits patient
- Technical challenges
  - Multiple / mixed ion sources required
  - Mass-charge ratio differs by 0.6 ‰ – challenge in synchrotron
  - Technical feasibility needs to be shown,  
i.e. stable injection, acceleration and extraction of mixed beam
  - Experimental investigation will start with separate ion beams at GSI this fall
