What is different?

Goran Perinić, AT-ECR

30.05.2007

Dear colleagues,

We are united here to celebrate the achievement of a collaboration in between science and industry. A collaboration for the construction of the world's largest cryogenic installation. An installation that is breaking many records!

However, before I talk about THIS collaboration, I should like to honour the achievements of ANOTHER collaboration that took place almost exactly 130 years ago:

Geneva 1877

Raoul Pictet

(1846-1929)

Pictet's apparatus for the liquefaction of oxygen
on the site of the
« Société genevoise de construction d'instruments de physique »

Fig. 1. — Grand appareil de M. Raoul Pictet pour la liquéfaction des gaz.

[...] Le joint du manchon et du manomètre est rendu absolument hermétique par le serrage à bloc d'un anneau de cuivre comprimé entre les deux surfaces planes du joint. Cet anneau s'aplatit légèrement et s'incruste dans ces deux surfaces d'une façon si intime qu'aucune fuite n'est à craindre. [...] extrait de R. Pictet: Mémoires sur la Liquéfaction de l'Oxygène (1878)

Théodore Turrettini

(1845-1916)

Goran Perinić, AT-ECR

30.05.2007

It was back in 1877 here in Geneva that Raoul Pictet, professor at the University of Geneva managed to liquefy oxygen. Pictet had in fact for the first time reached temperatures below 120 K ... CRYOGENICS WAS BORN.

The race for the liquefaction of the permanent gases and therefore the competition for ever lower temperatures in the second half of the 19th century must have been as exciting as the search for the Higgs Boson today.

As you imagine, Pictet did not build the apparatus for the liquefaction, that is shown on the drawing, himself. He contracted the construction to the engineer Théodore Turrettini who was the director of the Geneva society for the construction of physics instruments. The apparatus was built on the site of the “Geneva society for the construction of physics instruments” and used their steam engine as power source.

You will actually meet Théodore Turrettini again this evening: The Mandarin Oriental Hotel where tonight's reception takes place, is located on the Quai Turrettini. Once at the hotel, please do have a look across the Rhone to admire the « Bâtiment des Forces Motrices », Turrettini's most known oeuvre: the water pumping station of Geneva.

These guys, however fruitful their collaboration, did certainly not yet imagine the possible uses of low temperatures. They had just opened the door to a NEW WORLD ..., but I must come to CERN!

Let me make a leap of almost 100 years – a leap to our fathers and their collaborations:

CERN – BEBC to LEP

BEBC (1972)

immersion

OMEGA (1973)

supercritical He
with re-cooling

ISR (1976)

immersion

Goran Perinić, AT-ECR

30.05.2007

And I come to the historic of large superconducting coils at CERN.

These large superconducting coils that have been built by the collaborations of our fathers and I am sure that there are quite a few present here in the auditorium that have made those magnets work.

The refrigeration method is noted in blue. In those days it was very common to immerse the magnet into a liquid helium bath. This was advantageous for the refrigeration, but it required quite a considerable amount of helium. The first cool-down of the BEBC coil was in fact delayed due to a helium shortage. There were also other modes of refrigeration like the supercritical helium flow inside the OMEGA conductor.

From the 1970s to the 1980s:

CERN – BEBC to LEP

Dipole (1978)

18 mm

forced 2-phase flow

M1-EHS (1980)

1 R.C.B.C.
2 COILS
3 IRON YOKE
4 EXPANSION SYSTEM

14.8 mm

immersion

ALEPH (1987)

35 mm

thermosiphon

DELPHI (1988)

24 mm

forced 2-phase flow

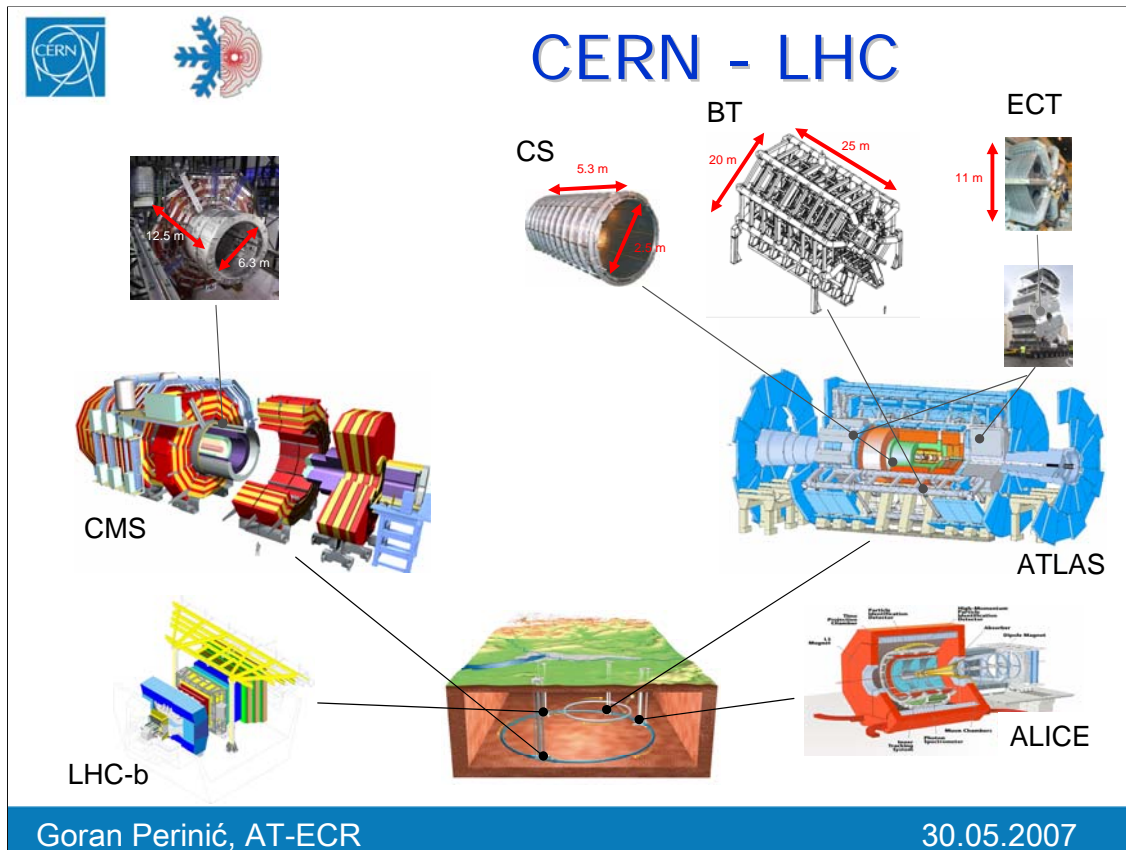

Goran Perinić, AT-ECR

30.05.2007

Two of these magnets, the DIPOLE and the M1-EHS magnet are still operational at CERN.

The ALEPH and DELPHI magnets of LEP were the models for the new magnets.

As you can see, CERN has collected quite a lot of experience in the field of large superconducting magnets before attacking the LHC project:

Goran Perinić, AT-ECR

30.05.2007

For LHC, as you know, four new detectors are being built. Two of them, Alice and LHC-b, are built with conventional magnets.

CMS comprises a large superconducting solenoid and

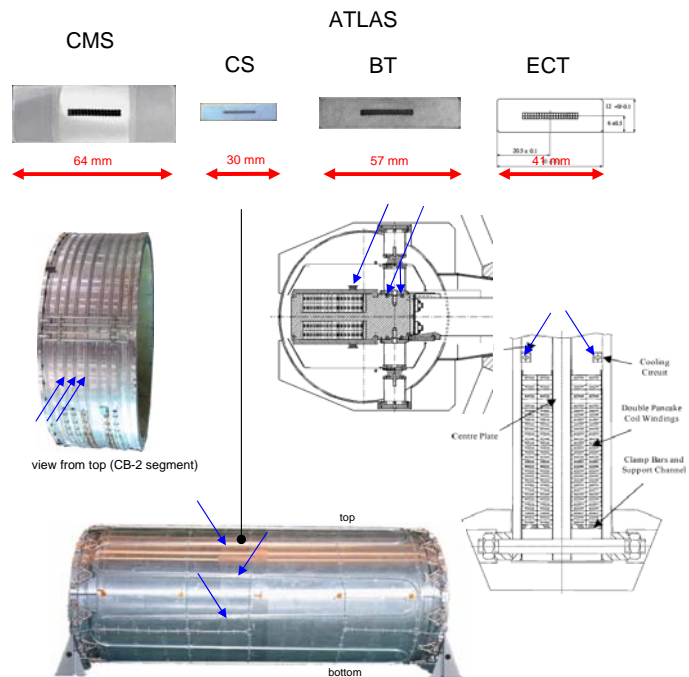

ATLAS contains a solenoid in the centre and a complex magnet system consisting of 24 toroidal coils.

What are the similarities and what are the differences in between these cooling systems for these coils?:

What is similar? I

- composite Al-stabilized conductors
- indirect cooling via the coil support
- operation temperature 4.5-4.8K
- cool-down with a maximum temperature gradient of 40K

Goran Perinić, AT-ECR

30.05.2007

I start with the similarities:

All coils are built using similar composite aluminium stabilized conductors.

In all cases the heat removal is achieved via the coil support.

All coils are operated at temperatures in the range from 4.5 K to 4.8 K.

And in all cases a maximum thermal gradient of 40 K is allowed during the cool-down.

What is similar? II

➤ materials and bonding

CMS

ATLAS-CS

ATLAS-BT

ATLAS-ECT

| | | | | |
|-------------------------|----------------------|-------------------|-------------------|---------------------|
| Coil support | Al 5083 H321 | Al 5083 | Al 5083 | Al 5083 |
| Cooling channels | Al 6060 T5 welded on | Al 6063 welded on | Al 1070 glued on | Al 6061 T4 glued on |
| Shield | Al 3003 H22 | Al | Al 3003 H22 | Al 5083 |
| Shield cooling channels | Al 6082 welded on | Al 6063 welded on | Al 1070 welded on | Al 1070 welded on |

Goran Perinić, AT-ECR

30.05.2007

Another point where the coils have many similarities are the materials chosen for the coil supports, the cooling pipes and the shields. All are in fact aluminium alloys. Why is it aluminium – because aluminium is more transparent to muons than copper or stainless steel.

The choice of the alloy depends on factors like heat conductivity, yield strength, weldability, extrudability.

Where are the differences? I

the helium circulation

CMS

thermosiphon
details in presentation
by P. Bredy

ATLAS-CS

forced 2-phase flow
+ thermosiphon
up to 7g/s driven by refrigerator

ATLAS-BT

common forced 2-phase flow
BT 700 g/s + ECT 2 x 250 g/s
driven by helium pump

ATLAS-ECT

Goran Perinić, AT-ECR

30.05.2007

The main difference in between the magnet coils is the method how the liquid helium is circulated:

CMS uses a thermosiphon system. It will be explained in detail in the next presentation by Philippe Bredy.

The ATLAS central solenoid uses directly the flow provided by the refrigerator. However, the cooling channels have been built in a way that thermosiphon cooling is possible in emergency cases too.

The ATLAS barrel toroid and end cap toroids are cooled in parallel with a forced two-phase flow driven by a dedicated liquid helium pump that has been specially developed.

Where are the differences? II

➤ the helium circulation

| | CMS | ATLAS-CS | ATLAS-BT/ECT |
|-----------------------------|--------------|-----------------|---------------------------------------|
| static heat load | 180 W | 11 W | BT 8x 80 W+ ECT 2x 200W |
| max. height difference | 12 m | 13 m | 20 m |
| cooling pipe dimensions | ⊗ 14 / 20 mm | ⊙ 18 / 24 mm | BT ⊗ 14 / 20 mm ECT ⊗ 15.7 / 24 mm |
| phase separator vol. | 800 l | 280 l | 4600 l |
| LHe inventory – phase sep. | 150 l | 180 l | 2700 l |
| LHe inventory – cool. pipes | 355 l | 30 l | BT 800 l + ECT 500 l |

Goran Perinić, AT-ECR

30.05.2007

Let me summarize some characteristic data:

1. The static heat loads are different as they depend on the size and shape of the coils.
2. All three cooling systems have to deal with height differences of more than 10 m.

And if you look at the last line:

3. The He inventories of the coils are comparatively small.

Where are the differences? III

the helium circulation

| | CMS | ATLAS-CS | ATLAS-BT/ECT |
|------------------------|--|-------------------------------------|-------------------------------------|
| ① $p_1; T_1;$ X_1 | 1,25 bar; 4,4 K (sat.) 0 % | 1,35 bar; 4,5 K (2-ph.) 5 % | 1,7 bar; 4,65 K (subc.) 0 % |
| mass flow | <u>200-400 g/s</u> | < 7 g/s | 700 g/s + 500 g/s |
| ② $p_2; T_2;$ X_2 | 1,25 bar; 4,4 K (2-ph.) <u>up to 10 %</u> | 1,3 bar; 4,5 K <u>up to 33 %</u> | 1,67 bar; 4,8 K <u>up to 8 %</u> |

■ values vary in dependency of the heat load (static load, dynamic load)

Goran Perinić, AT-ECR

30.05.2007

Here are the conditions at the inlet and at the outlet of the coil cooling circuits.

What are the thermodynamic differences of the three cooling methods?

In the case of CMS the refrigeration starts with a saturated liquid. Variations in the heat load, i.e. when a coil is charged or discharged, make vary the helium flow.

In the ATLAS central solenoid the starting point is two-phase helium and the vapour content at the outlet varies in dependency of the heat load.

In the barrel toroid and the end cap toroid the situation is similar only that the starting point is sub-cooled helium at 1.7 bar.

Conclusion

Four new superconducting magnets have been built for the LHC experiments thanks to an extensive collaboration in between CERN, external institutes and industrial suppliers. The new magnets surpass anything built before at CERN and elsewhere.

The magnet cooling methods have been chosen in dependency of the magnet design. They represent a consistent development of the technologies and experiences gained from previous projects at CERN.

The cooling systems have been designed and built for the long term operation.

Thank you!
