Radiation tolerant small-pixel passive CMOS sensors with RD53A readout

Friday 5 June 2020 13:00 (20 minutes)

With the HL-LHC upgrade of the ATLAS detector, the surface of the ATLAS pixel detector will increase from 2 m² to approximately 13 m². Therefore, commercial CMOS processing lines offering high production throughput at comparatively low costs represent an attractive option for such large-area detectors. Further benefits originate from multiple metal layers, metal-insulator-metal capacitors, and polysilicon layers which can be used to enhance the sensor design.

Thinned, small-pixel passive CMOS sensors in 150 nm technology offered by LFoundry were manufactured and assembled into hybrid pixel modules using the RD53A readout chip.

The sensors were characterized, before and after irradiation to a fluence of 5×10^{15} n_{eq}/cm², in the laboratory and also using a minimum ionising electron beam. Their performance in terms of noise and hit-detection efficiency equals that of conventional planar pixel sensors. In particular, a hit-detection efficiency of 99 % is measured after irradiation to 5×10^{15} n_{eq}/cm².
