CMS @ the LHC

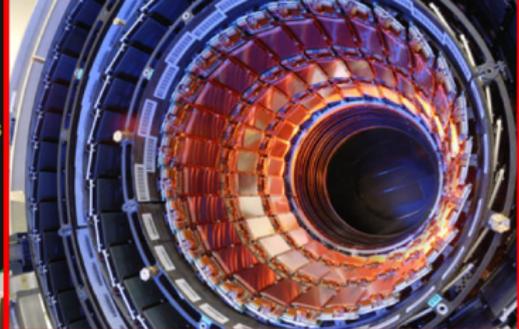

Luminosity in p+p

- CMS expects to integrate around 40 pb^{-1} by the end of the 2010 p+p run with an overall data taking efficiency better than 91%. Now recording $\sim 3.5 \text{ pb}^{-1}/\text{good fill}$.
- LHC instantaneous p+p luminosity already reached $10^{32} \text{ cm}^{-2}\text{s}^{-1}$
 - CMS trigger paths frequently upgraded to keep a tolerable rate
 - Low p_T dimuon triggers in 2010 optimized for J/ψ and Υ physics

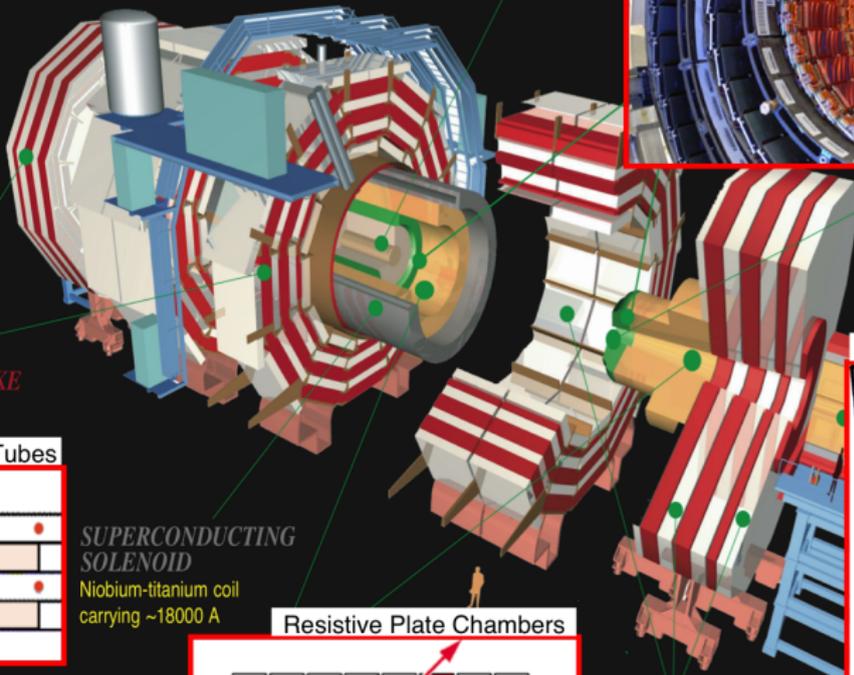

CMS Detector

SILICON TRACKER
Pixels ($100 \times 150 \mu\text{m}^2$)
~1m² ~66M channels
Microstrips (80-180 μm)
~200m² ~9.6M channels

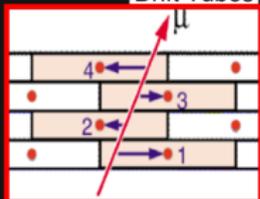

Pixel and Strip Silicon Tracker

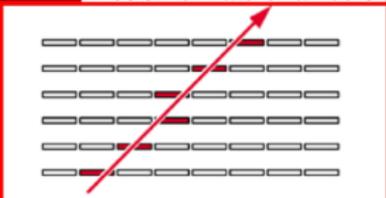

STEEL RETURN YOKE
~13000 tonnes

Drift Tubes

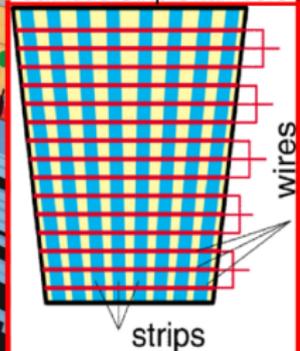

SUPERCONDUCTING SOLENOID
Niobium-titanium coil
carrying ~18000 A

Resistive Plate Chambers

Cathode Strip Chambers

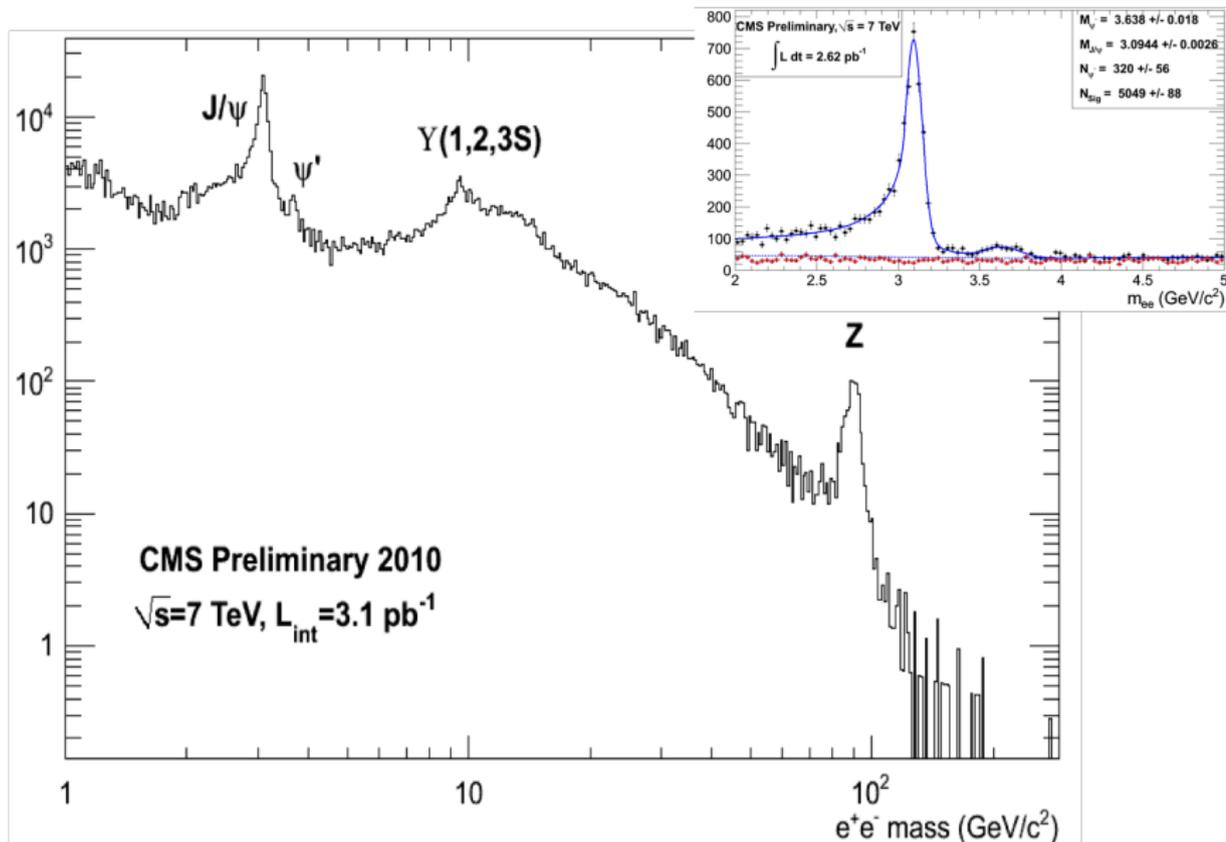

Total weight : 14000 tonnes
Overall diameter : 15.0 m
Overall length : 28.7 m
Magnetic field : 3.8 T

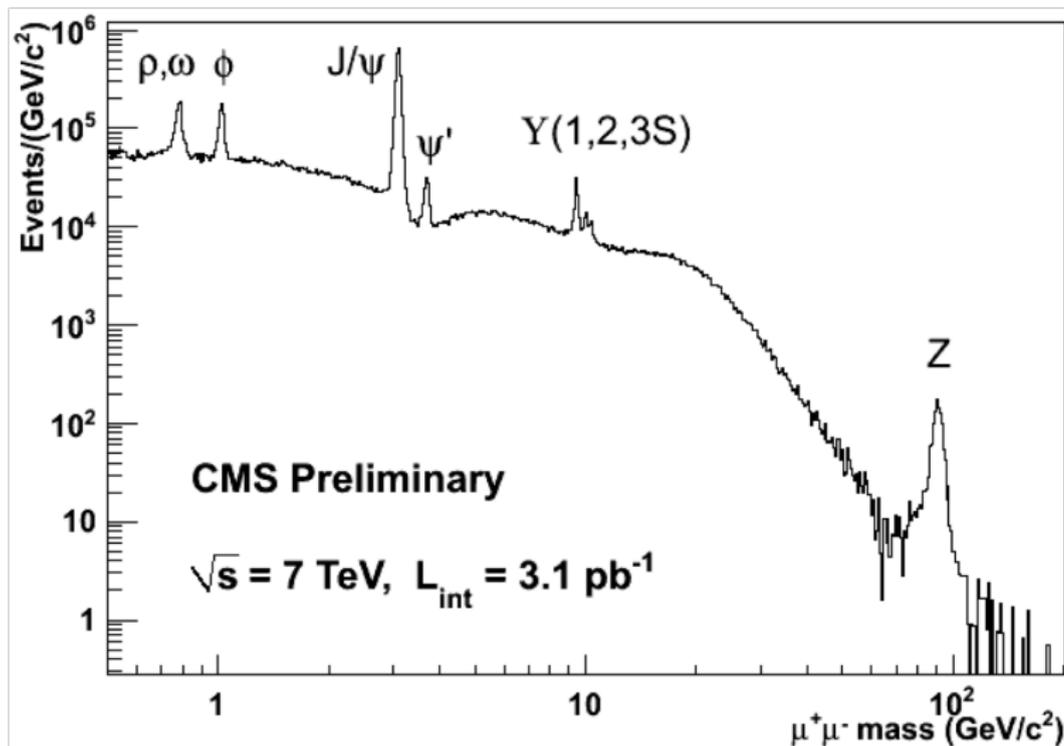

MUON CHAMBERS

Barrel: 250 Drift Tube & 480 Resistive Plate Chambers
Endcaps: 473 Cathode Strip & 432 Resistive Plate Chambers

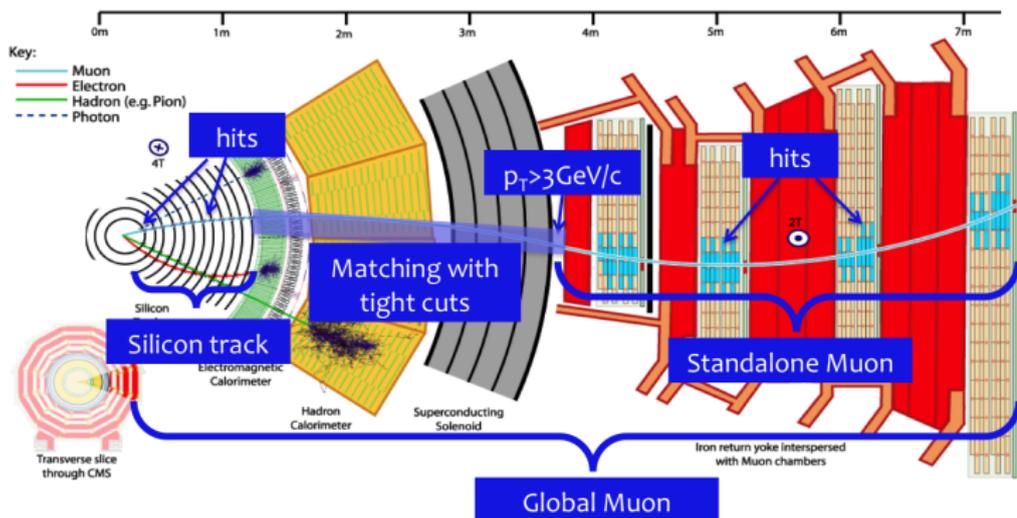

Di-Electrons

The Compact (di-)Muon Solenoid Experiment

Muon Reconstruction

Good muon momentum resolution

- Tight matching between the tracks in the muon chambers and in the silicon tracker
- Strong solenoidal magnetic field (3.8T)
- Large rapidity coverage ($|\eta| < 2.4$)

$$p_T = 100 \text{ GeV}, \sigma_p^\mu \sim 1\%$$

$$p_T = 1 \text{ TeV}, \sigma_p^\mu \sim 10\%$$

Ideal to measure dimuons

- Excellent dimuon mass resolution: varies as a function of η due to increasing material and of the different lever arm a track has above $\eta \sim 1.6$

$$|\eta| < 2.2, \sigma_{mass}(J/\psi) \approx 40 \text{ MeV}$$

$$|\eta| \approx 0, \sigma_{mass}(J/\psi) \approx 20 \text{ MeV}$$

Cross-Section Determination in $p+p$

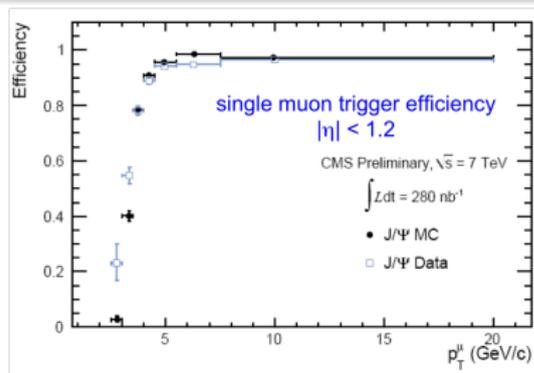

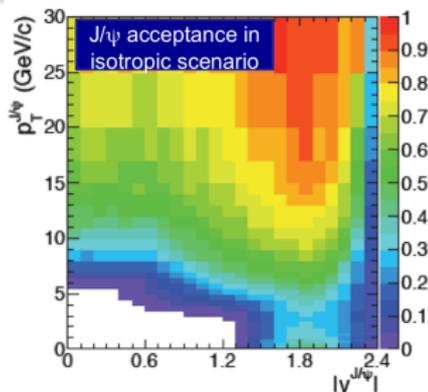

$$\frac{d^2\sigma}{dp_T dy}(Q\bar{Q}) \cdot \text{BR}(Q\bar{Q} \rightarrow \mu^+\mu^-) = \frac{N_{Q\bar{Q}}}{\int \mathcal{L} dt \cdot A \cdot \epsilon_{\text{trigger}} \cdot \epsilon_{\text{reco}} \cdot \Delta p_T \cdot \Delta y}$$

Acceptance calculated by MC and depends on the assumed polarization scenario:

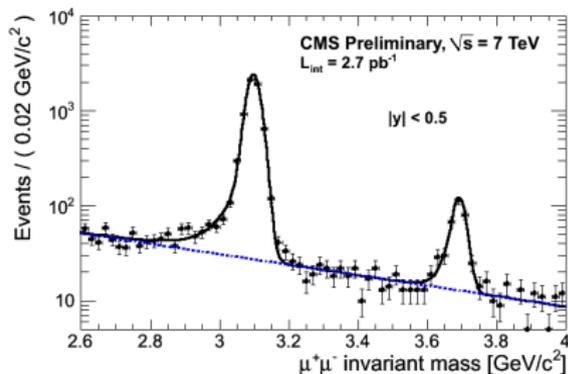

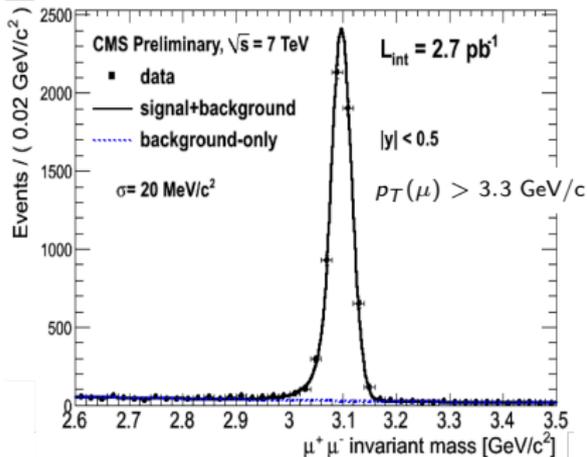

- isotropic
- extreme values of λ_θ ($= \pm 1$) in the helicity frame (along the Q momentum)
- extreme values of λ_θ ($= \pm 1$) in the Collins-Soper frame (along the collision axis)

Efficiency determined with a data-driven (tag-and-probe) method

- take a well-identified muon in the event (tag)
- take another candidate muon, with looser criteria (probe)
- efficiency = fraction of all tag-probe pairs where the probes pass a given selection

J/ ψ \rightarrow $\mu^+ \mu^-$ in p+p at 7 TeV

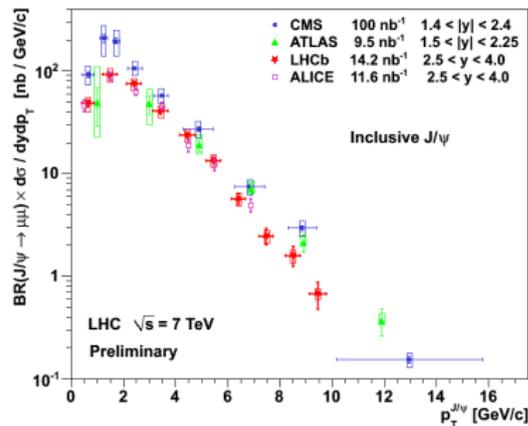

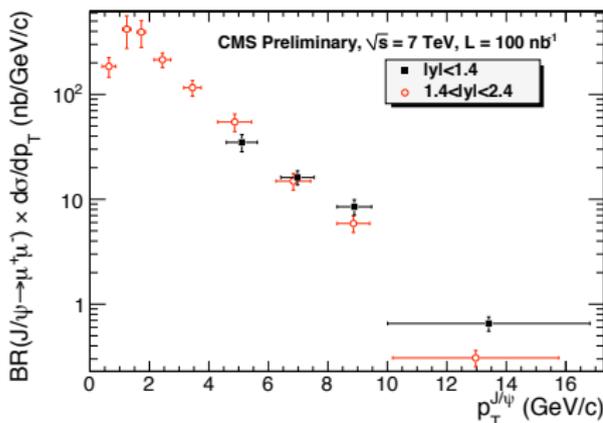

Excellent tracking performance

- B=3.8T
- Tracking resolution: $0.015\% p_T \oplus 0.5\%$
- CMS will collect unprescaled low p_T dimuon triggers up to the end of the p+p run

J/ψ Inclusive Cross-Section in p+p

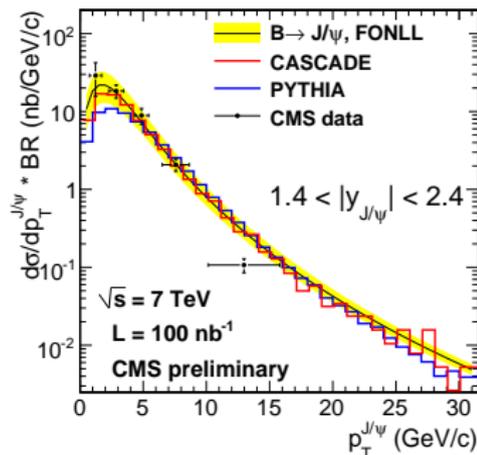

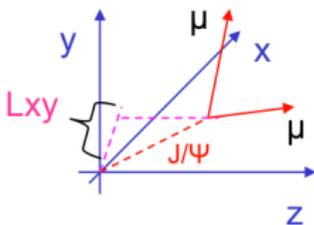

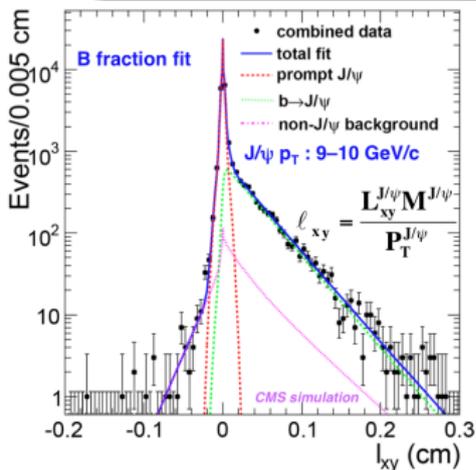

From first 100 nb⁻¹

- Measured vs. p_T at mid and forward rapidity
- Assuming no polarization, for $p_T > 4$ and $|y| < 2.4$:
 $\sigma(pp \rightarrow J/\psi + X) \cdot \text{BR}(J/\psi \rightarrow \mu^+ \mu^-) = 289.1 \pm 16.7(\text{stat}) \pm 60.1(\text{syst}) \text{ nb}$
- Selection : Vertexing prob. of $\mu^+ \mu^- > 0.1\%$, high quality tracks associated to the muon segments : cuts on n_{hits} , χ^2 , $|dxy|$, $|dz|$

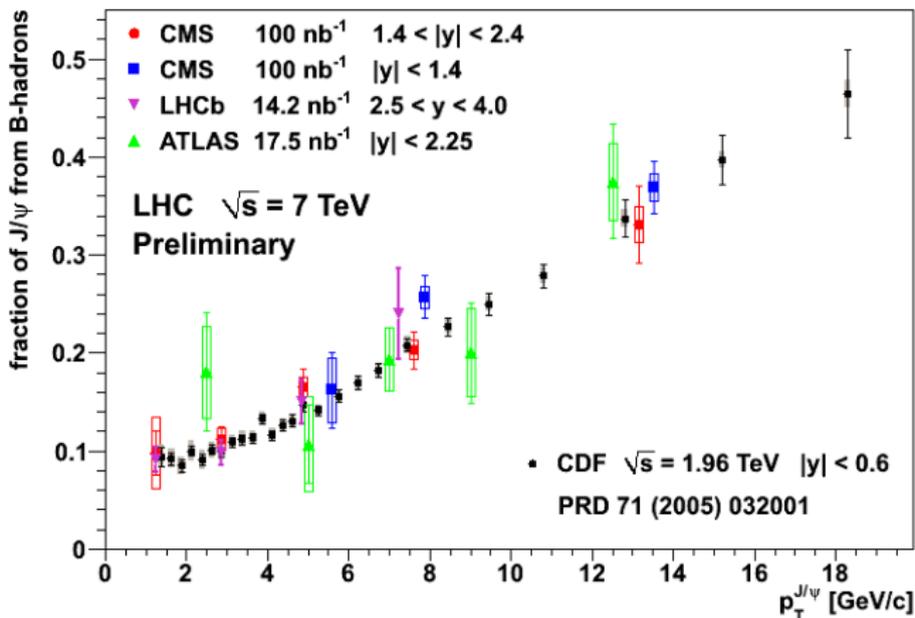

Prompt and Non-Prompt J/ψ

- Thanks to its very good tracking performance, CMS measures the distance between the interaction vertex and the dimuon vertex with a resolution around 50 micron
- The prompt and non-prompt components are obtained from a 2D fit to the dimuon mass and pseudo-proper decay length $l_{J/\psi} = L_{xy} \cdot m_{J/\psi} / p_T$
- Decay length parameterization: prompt (δ -function) and non-prompt (MC templates) convoluted with a 3-Gaussian resolution
- $\sigma(pp \rightarrow b \rightarrow J/\psi X) \cdot B(J/\psi \rightarrow \mu^+ \mu^-) = 56.1 \pm 5.5(\text{stat}) \pm 7.2(\text{syst}) \text{ nb}$

B Hadron Decay Feed Down

- The B fraction is not very sensitive to the J/ψ rapidity
- Nor to the collision energy (above 2 TeV)

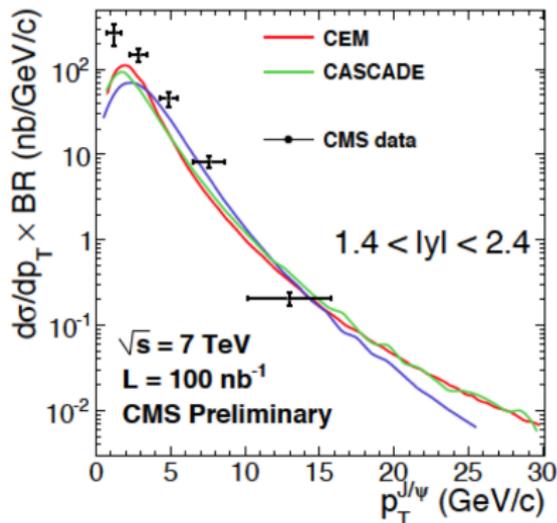

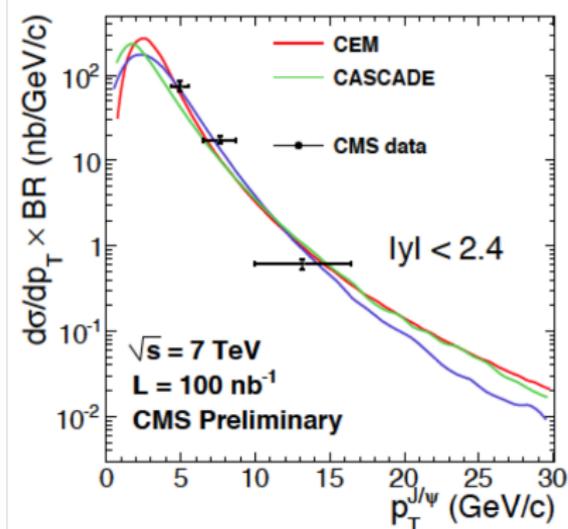

Prompt J/ψ Cross-Section

From first 100 nb⁻¹

- The J/ψ prompt cross section has been measured vs. p_T at mid and forward rapidity
- Assuming no polarization, for $p_T > 4$ and $|y| < 2.4$:

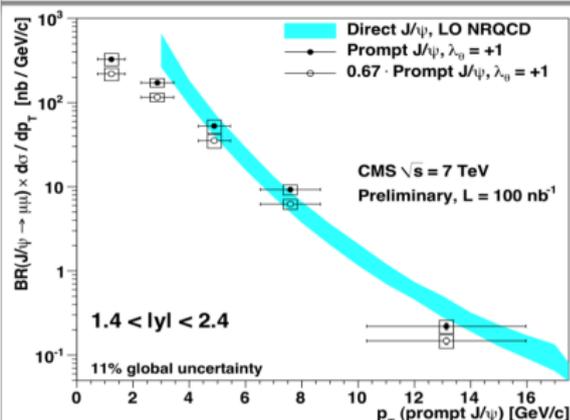

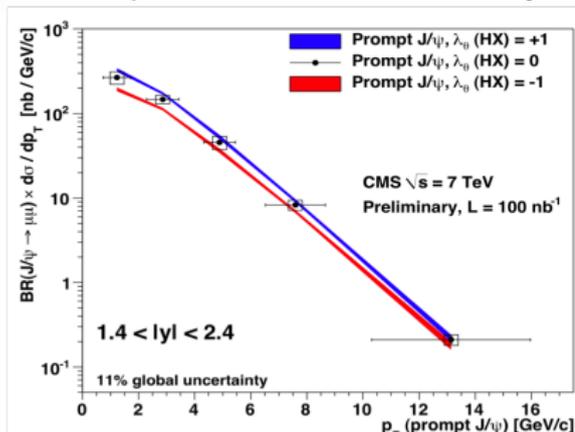

$$\sigma(pp \rightarrow J/\psi + X) \cdot \text{BR}(J/\psi \rightarrow \mu^+ \mu^-) = 289.1 \pm 16.7 \pm 60.1 \text{ nb}$$

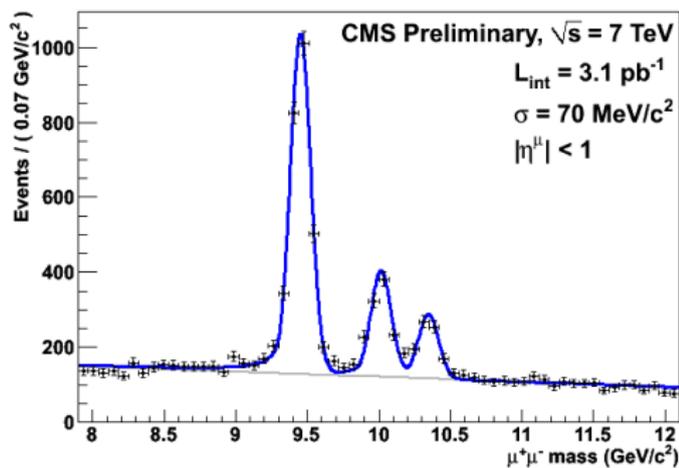

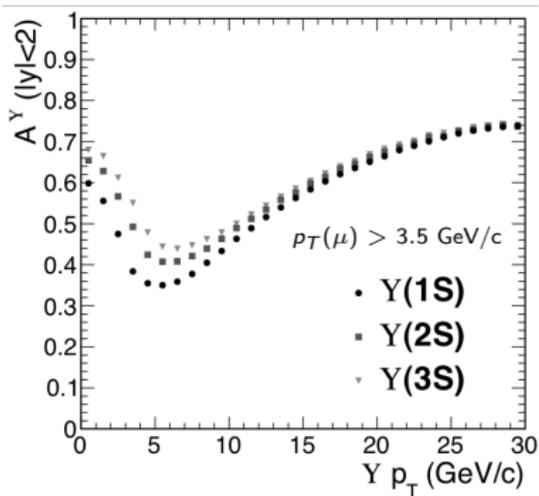

Prompt J/ ψ Cross-Section

Effect of polarization

- The measured J/ ψ cross-section depends on the assumed polarization
 - NRQCD predicts transverse polarization, growing with p_T
 - CSM predicts longitudinal polarization, flat with p_T
 - CEM calculations, so far, do not address polarization issues
- NRQCD & CSM curves only include the direct cross sections while the data includes feed-down terms from ψ and χ_c decays (around 33%)
- No (reliable) predictions for the ψ' , χ_{c1} and χ_{c2} differential cross-sections or polarization, which are likely to change with $p_T \Rightarrow$ data-driven field

$\Upsilon \rightarrow \mu^+ \mu^-$ in p+p at 7 TeV

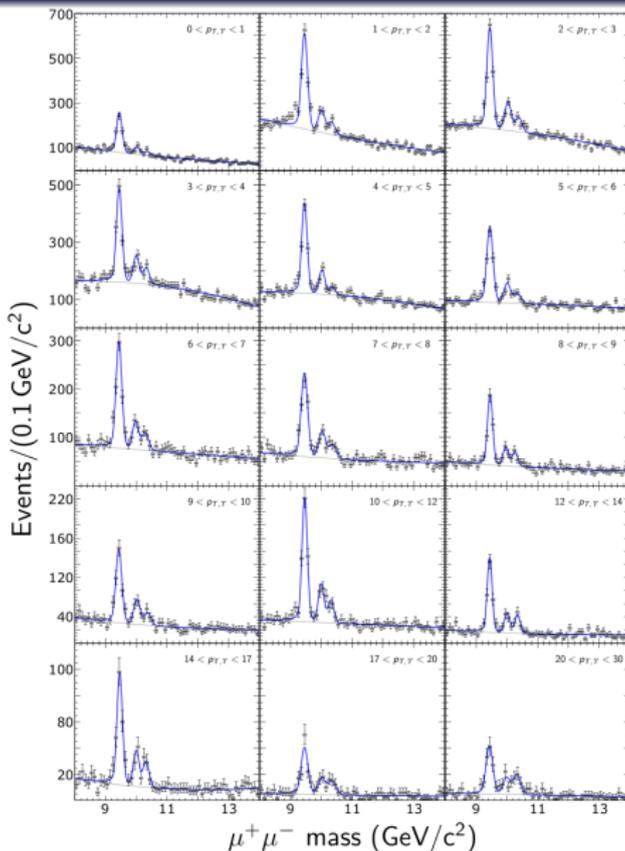

Performance

- CMS has a very good acceptance for Υ dimuons, even at very low p_T
- The mass distribution is ~ 100 MeV integrating over full rapidity ($|y| < 2.4$) and ~ 70 MeV in the barrel ($|\eta(\mu)| < 1$, for each of the two muons)

$\Upsilon \rightarrow \mu^+ \mu^-$ in p+p at 7 TeV

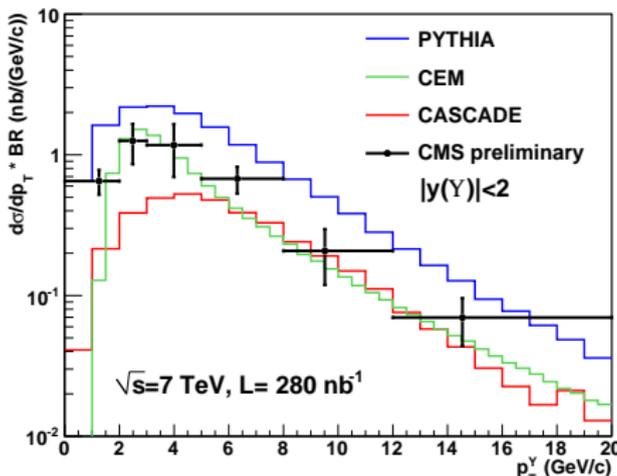

- 15 bins in p_T
- Disentangling Υ states even at $p_T = 30$ GeV/c !

Υ Cross-Section in p+p

From first 280 nb⁻¹

- Muons well within acceptance window ($|y| < 2.0$)
- Similar quality selection as J/ψ
- The Υ (1S) differential cross section has been measured vs. p_T
- Integrated over $|y| < 2.0$ (value assuming no polarization):
 $\sigma(\Upsilon(1S)) \cdot BR(\Upsilon(1S) \rightarrow \mu^+ \mu^-) = 8.3 \pm 0.5(stat) \pm 0.9(syst) \pm 1.0(lumi)$ nb

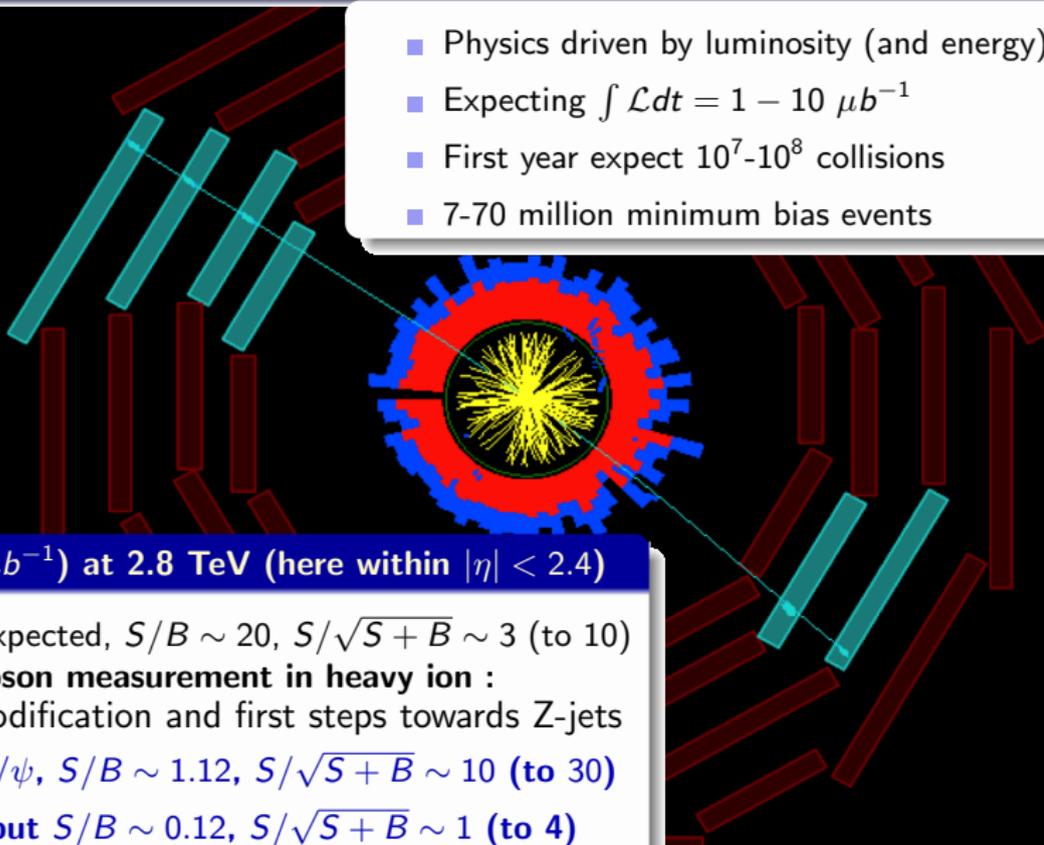

First Measurements in Heavy Ions

SIMULATION

- Physics driven by luminosity (and energy)
- Expecting $\int \mathcal{L} dt = 1 - 10 \mu b^{-1}$
- First year expect $10^7 - 10^8$ collisions
- 7-70 million minimum bias events

For $\mathcal{L} = 1$ (to $10 \mu b^{-1}$) at 2.8 TeV (here within $|\eta| < 2.4$)

- 10 (100) Z^0 expected, $S/B \sim 20$, $S/\sqrt{S+B} \sim 3$ (to 10)
First weak boson measurement in heavy ion :
 - PDF modification and first steps towards Z-jets
- **250 (2500) J/ψ** , $S/B \sim 1.12$, $S/\sqrt{S+B} \sim 10$ (to 30)
- **30 (300) Υ** , but $S/B \sim 0.12$, $S/\sqrt{S+B} \sim 1$ (to 4)

Triggers

Strategy

Finalizing triggering scheme, customized trigger menu both at L1 and at High Level Trigger (HLT)

- Expect up to 50-140 Hz collisions. Maximum disk writing limit is 150 Hz (200 Hz with no Tier-0 transfers)
- Aim to record all collisions
- Preparing HLT trigger menus to deal with possible luminosity scenarios
- Arranging data streams, alignment and calibration etc.
- Optimize data streams for HI physics plans

Summary and Prospects

In p+p

- Already spectacular quarkonia results with the CMS detector
- Expecting to have collected enough statistics by the end of the p+p run (around 2.5 M J/ψ and 100 000 Υ (1S)) to study much more :
 - J/ψ and Υ polarization, in several p_T and y bins
 - χ_c over J/ψ cross-section ratio, using calorimeter-seeded photons
 - χ_{c1} over χ_{c2} cross-section ratio, using tracker-seeded photon conversions

In HI

- We have been making steady progress on preparations
- The accelerator schedule and expected performance is quite uncertain, we are being conservative in our expectations
- We expect to collect non-zero-suppressed p+p data, this will provide important input to preparations
- Plans for calibrations, trigger, computing have been settled
- We are ready to collect and analyze first heavy ion data from LHC
