

# Searching for local group supernovae using high-energy neutrinos from CSM interaction

*Tuesday, November 24, 2020 3:36 PM (3 minutes)*

IceCube monitors our galaxy for supernovae using neutrinos with energies of tens of MeV. However, the shock between the ejecta and the progenitor star's circumstellar material can create a high flux of neutrinos with energies on the order of TeV and above. These neutrinos would reach Earth 0.1 day - 1 year after the low-energy neutrinos. I will describe an analysis aimed to investigate whether we can extend IceCube's observational reach by using these high-energy neutrinos and design a search for hidden SN in our local group.

## **Abstract Track**

Flash talk, Astroparticle physics
