

Bunch shape monitors with RF scanning of low energy secondary electrons

A.V.Feschenko

**Institute For Nuclear Research (INR),
Moscow 117312, Russia**

For complete beam description a behavior of a 6-dimensional distribution function in time is required

$$j(x, x', y, y', \varphi, W, t)$$

Beam Current Transformer:

$$J(t) = \int j(x, x', y, y', \varphi, W, t) dx dx' dy dy' d\varphi dW$$

Wire scanner:

$$J(x, t) = \int j(x', y, y', \varphi, W, t) dx' dy dy' d\varphi dW$$

Horizontal emittance detector:

$$J(x, x', t) = \int j(y, y', \varphi, W, t) dy dy' d\varphi dW$$

.....etc.....

Process of acceleration can be described as a behavior of particles in Energy-Phase plane (W, φ)

that is why

the beam distribution functions versus W and (or) φ are extremely important and interesting.

However, they are the most difficult to measure.

Energy Spectrum:

$$J(W, t) = \int j(x, x', y, y', \varphi, W, t) dx dx' dy dy' d\varphi$$

Phase Spectrum (Bunch Shape):

$$J(\varphi, t) = \int j(x, x', y, y', W, t) dx dx' dy dy' dW$$

Longitudinal phase space distribution:

$$J(\varphi, W, t) = \int j(x, x', y, y', W, t) dx dx' dy dy'$$

The main requirement for Bunch Shape Measurements is **Phase Resolution**

For typical Bunch Phase Durations $\sim 10^\circ$ phase resolution must be about 1°

For $f=400$ MHz phase resolution of 1° is equivalent to time resolution of **7 ps**.

The equivalent bandwidth: $\Delta F = 72$ GHz.

Basic Limitation of Band Width of detectors using transfer of information about longitudinal distribution through beam electromagnetic field.

For $W=100$ MeV and $R=2$ cm

$\Delta F=2.5$ GHz.

Configuration of electric field of point charge moving in a metal pipe.

The way out is localization of space region where the information transfer occurs.

There are different possibilities to shrink the area of information transfer:

- 1. Cherenkov radiation;**
- 2. Detached electrons in case of H- (including photo-detachment);**
- 3. δ -electrons;**
- 4. Transition radiation;**
- 5. X-rays;**
- 6. Low energy secondary electrons;**
- 7. etc.**

The main characteristics of Low Energy Secondary Electrons influencing BSM parameters

- Energy distribution
- Angular distribution
- Time dispersion (delay of emission)

These characteristics depend neither on type nor on energy of primary particles

Time dispersion is principal reason of limitation of BSM phase resolution.

Theoretical value of time dispersion for metals is $10^{-14}\text{s} \div 10^{-15}\text{s}$.

Experiment gives the upper limit of time dispersion. Depending on the accuracy the upper limit was found to be from $(4 \pm 2)\text{ps}$ to several hundred ps.

Transverse Circular Modulation

Configuration of INR Bunch Shape Monitor

1 - target, 2 - input collimator, 3 - rf deflector combined with electrostatic lens, 4 - output collimator, 5 – collector of electrons

Example of electron trajectories

Trajectories for optimum focusing and rf deflection off

Trajectories electrons efor two groups of electrons entering rf deflector at different phases (phase difference equals 5° at $f=1300$ MHz)

Evaluation of phase resolution

Displacement of electrons at output collimator

$$Z_L = Z_{\max} \sin \varphi$$

Phase resolution

$$\Delta\varphi = \frac{\Delta Z_L}{Z_{\max}}$$

where ΔZ_L - full width at a half maximum of electron beam size for a δ -function bunch, Z_{\max} – amplitude of electron displacement at output collimator.

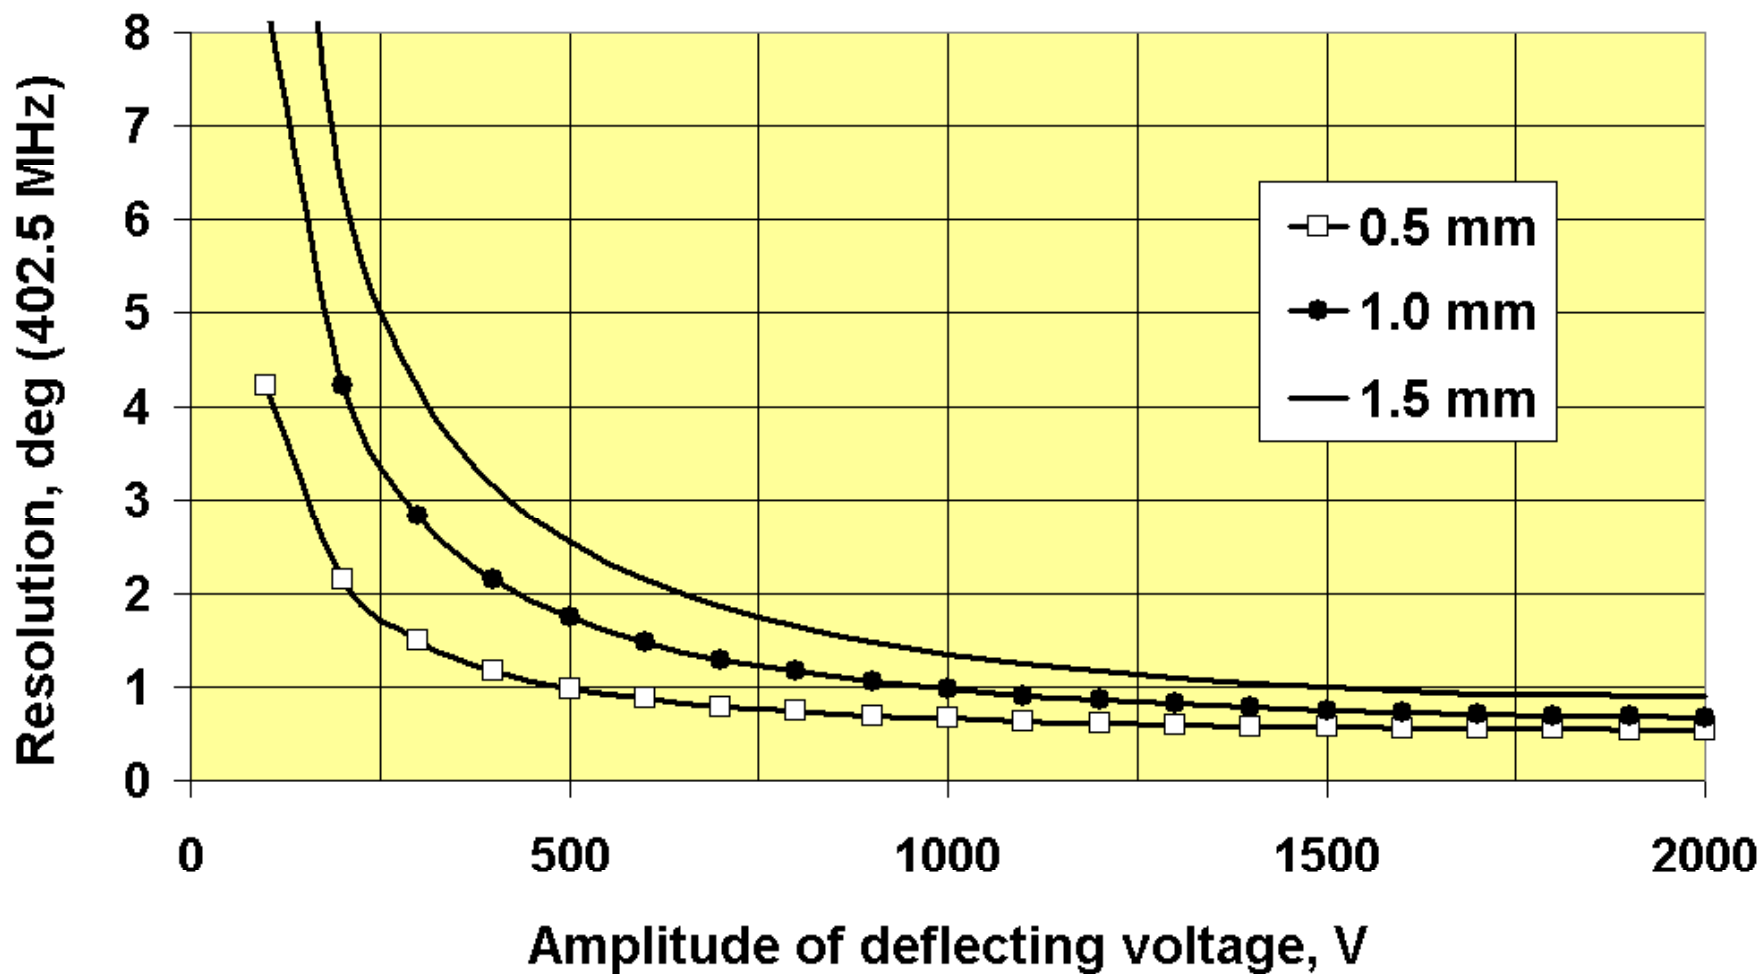

In practice we use:

$$\Delta\varphi = \frac{\sqrt{(2\sigma)^2 + (\Delta Z_0)^2}}{Z_{\max}}$$

where ΔZ_0 – focused beam size observed experimentally for rf deflection off, σ – rms size of the focused electron beam for a δ -function bunch

Dependence of Phase Resolution on Amplitude of Deflecting Voltage for different Input Collimators

Influence of analyzed beam space charge

Two main effects:

- **Increasing of the focused beam size. This effect results in aggravation of phase resolution.**
- **Changing of the average position of the focused electron beam at the output collimator. This effect is the reason of the error of phase reading.**

Model 1 implies that the boundary conditions are kept constant while the bunch passes the detector chamber. The fields are found by multiple solving of a Poisson equation in the beam frame for fixed bunch positions as the bunch passes the chamber. Electrostatic fields found in the beam frame produce both electric and magnetic components in the lab frame. The field effecting secondary electrons is represented as a superposition of electromagnetic field of the bunch and an unperturbed electrostatic field due to target HV potential (-10 kV). We suppose that the target potential is kept invariable and hence the model is valid if the time of flight of the bunch through the wire $\Delta\Phi/(360f)$ is essentially smaller than the time of signal propagation from the target center to the holders $L/(2c)$. Here $\Delta\Phi$ is the bunch duration (deg), f - bunch repetition frequency, L - target length and c - velocity of light. In our case $L=45$ mm and the model is supposed to be valid for $\Delta\Phi$ essentially larger than 10° .

Model 2 is used if $\Delta\Phi/(360f)$ is smaller than $L/(2c)$. Electrostatic fields of the bunch in the beam frame are found by Poisson equation multiple solving for boundary conditions with the target absence. The field effecting secondary electrons is found similarly to the first model as a superposition of electromagnetic field of the bunch and an unperturbed electrostatic field due to HV potential applied to the target.

Influence of analyzed beam space charge

Distance passed by electron versus time and electron energy versus distance

Energy deviation and time of flight of electron from target to input collimator $W=200$ MeV, H-minus, $\sigma_y=1.2$ mm, $\sigma_z=1.2$ mm, $\sigma_\phi=1.1^\circ$, $Z_0=0$ mm, $f=366$ MHz (Model #2)

Influence of analyzed beam space charge

Resolution and phase reading error for $W=3$ MeV H-minus, $\sigma_y=2.6$ mm, $\sigma_z=2.6$ mm, $\sigma_\phi=13^\circ$, $Z_0=0$ mm, $f=366$ MHz (Model #1)

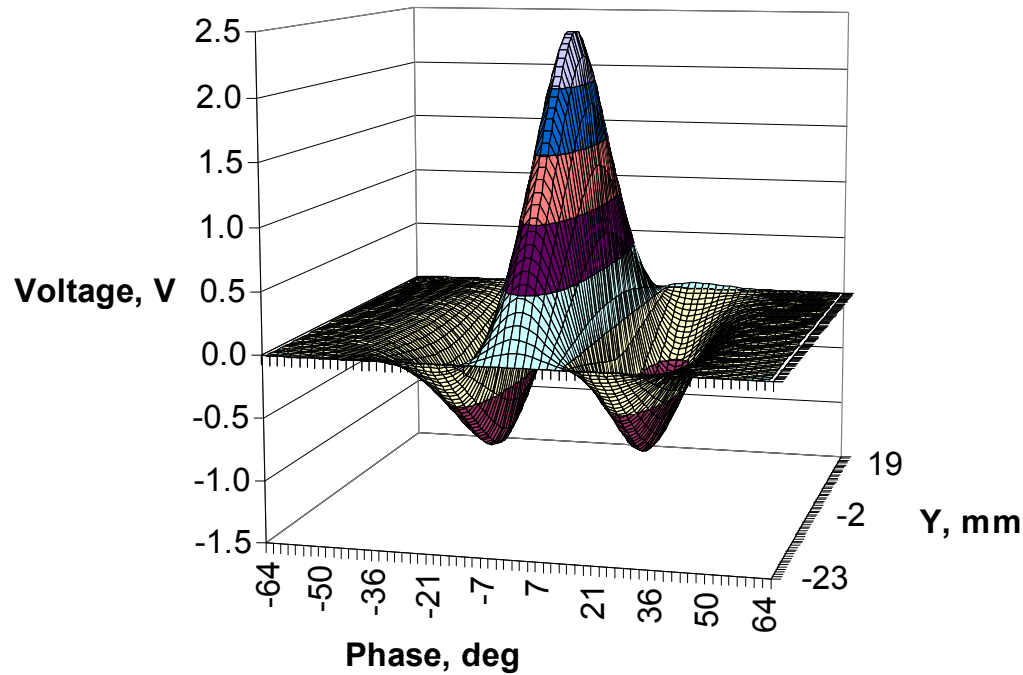

Resolution and phase reading error for $W=200$ MeV, H-minus, $\sigma_y=1.2$ mm, $\sigma_z=1.2$ mm, $\sigma_\phi=2.1^\circ$, $Z_0=0$ mm, $f=366$ MHz (Model #2)

Influence of currents induced in the target by an analyzed beam

$$\frac{\partial U(y, t)}{\partial y} = L \frac{\partial i(y, t)}{\partial t} + Ri(y, t)$$

Result of calculation of target voltage variation for 150 mA CERN Linac-2 beam

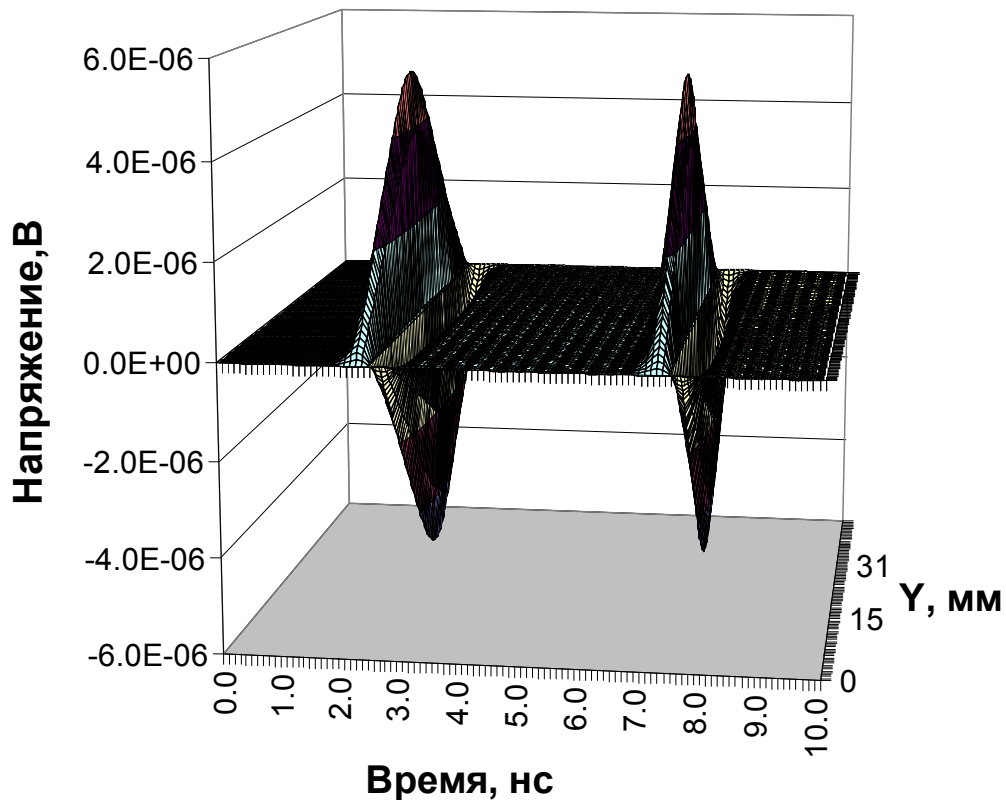

Influence of secondary emission current

$$\frac{\partial^2 U}{\partial y^2} - LC \frac{\partial^2 U}{\partial t^2} - RC \frac{\partial U}{\partial t} = RI + L \frac{\partial I}{\partial t}$$

Transmission line current generator due to secondary emission

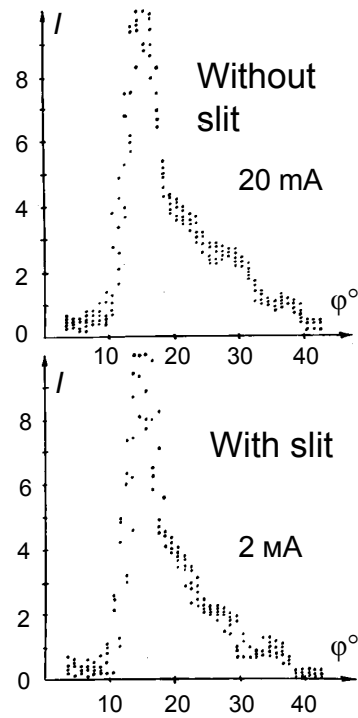

$$I(y, t) = \frac{I_0 T}{2\pi\sigma_y\sigma_t} e^{-\frac{\left(t-\frac{T}{2}\right)^2}{2\sigma_t} - \frac{(y-y_0)^2}{2\sigma_y}}$$

Summary

Bunch shape monitors with RF scanning of low energy secondary electrons are used for longitudinal parameters measurements of beams of different particles (protons, H-minus ions, heavy ions) within the energy range from several MeV to 1 GeV. The accuracy of measurements is about 1° at several hundred MHz.
