

# Long-lived particles at CLIC

**Ulrike Schnoor (CERN)**

Erica Brondolin, Cecilia Ferrari, Emilia Leogrande

CLICdp Meeting 2020

- ▶ Various new physics models predict particles with macroscopic lifetimes
- ▶ Example: Small mass splitting/compressed spectra
- ▶ “Standard” analyses lack sensitivity
- ▶ Variety of signatures in detectors depending on the model (mass, lifetime, boost)
- ▶ Long-lived particles at LHC:
  - ▶ LHC LLP overview report: [1903.04497](https://arxiv.org/abs/1903.04497)
  - ▶ Many ongoing analyses
  - ▶ Proposed dedicated experiments (e.g. FASER)
- ▶ Physics beyond colliders: [1901.09966](https://arxiv.org/abs/1901.09966)

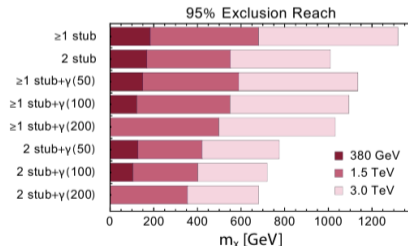

## 1. Hidden valley searches in Higgs boson decay

- ▶ displaced multi-track vertices
- ▶ full simulation study with CLIC\_ILD  
[CLICdp-Note-2018-001](#)

## 2. Degenerate Higgsino Dark Matter

- ▶ Theory-level study for the CLIC Potential for New Physics yellow report [[1812.02093](#)] by N. Craig and S. Alipour-Fard
- ▶ Process: chargino pair production
- ▶ Stub tracks from charged Higgsino with a lifetime of 6.9 mm
- ▶ Decay to pion and neutralino
- ▶ Using geometrical detector acceptance and minimum reconstructable length for the efficiency of reconstructing the stub tracks

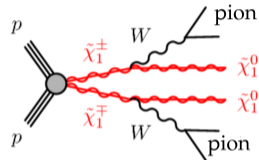

- ▶ Analysis with 1 or 2 stubs and possibly additional photon at 3 TeV
- ▶ Resulting exclusion limits assuming no background:

(Fig. 74 from the YR)

- ▶ Reach thermal DM mass of  $\approx 1$  TeV

- ▶ Process: chargino pair production where the  $\chi_1^\pm$  decay to a neutralino and a pion:  $e^+e^- \rightarrow \tilde{\chi}_1^+ \tilde{\chi}_1^- \rightarrow \tilde{\chi}_1^0 \pi^+ \tilde{\chi}_1^0 \pi^-$
- ▶ CLICdet at 3 TeV, with ISR and Beamspectrum included
- ▶ Small mass difference between chargino and neutralino: Chargino mass  $m_{\tilde{\chi}_1^\pm} = 1050$  GeV, neutralino mass  $m_{\tilde{\chi}_1^0} = 1049.645$  GeV
- ▶ Production chain:
  - ▶ Chargino pair production and decay in Whizard
  - ▶ Parton shower and hadronization in Pythia
  - ▶ Displacement of the decay vertex in Geant4

chargino mixing	thermal limit mass	mass difference	lifetime	$c\tau$	$\Gamma$
pure higgsino	1050 GeV	355 MeV	0.023 ns	6.9 mm	$2.86 \times 10^{-14}$ eV

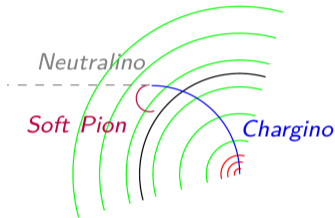

- ▶ Sample produced for the studies shown here uses lifetime of 600 mm in order to increase the statistics of reconstructable charginos

# Analysis strategy

Stub track analysis at 3 TeV with CLICdet

## Signal selection

- ▶ Stub track candidate definition:
  - ▶ at least four hits in the tracking system
  - ▶ disappearing within the tracking system volume
  - ▶ no energy deposition in the calorimeter
  - ▶ prompt, isolated track
  - ▶ minimum transverse momentum
  - ▶  $dE/dx$  requirement
- ▶ At least one stub candidate per event
- ▶ Additional: Requirements on soft displaced pion(s)
- ▶ Additional: Requirements on additional photons

## Backgrounds:

- ▶ Beam-induced  $\gamma\gamma \rightarrow$  hadrons:
  - ▶ algorithmic
  - ▶ split tracks
  - ▶ conversion
- ▶ final states with low multiplicity of isolated leptons

# Track reconstruction for the analysis

2 challenging types of objects for track reconstruction with conformal tracking:

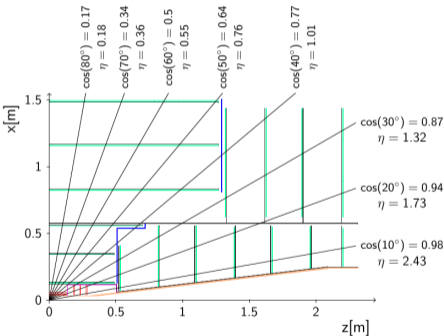

## ► Stub track reconstruction

- in many cases too short to be reconstructable
- at CLIC 3 TeV:  $E_{\text{max}} = 1.5 \text{ TeV}$ ,  $m = 1.05 \text{ TeV}$   
 $\Rightarrow p_{\text{max}} \approx 1.07 \text{ TeV}$

$\Rightarrow$  chargino gives very straight and short track  $\Rightarrow$  difficult to reconstruct track parameters

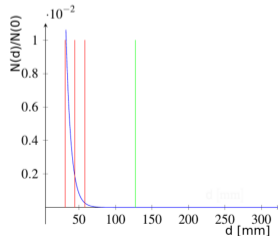

## ► Displaced pions

- very soft
- displaced

CLICdet vertex & tracker

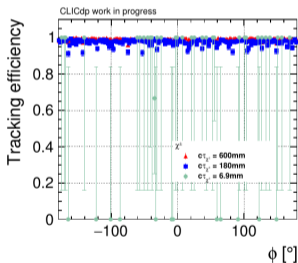

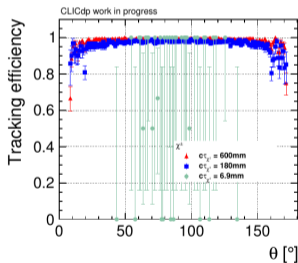

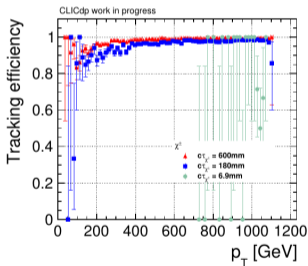

*chargino lifetime distribution at  $\theta = 90^\circ$  for  $c\tau = 6.9 \text{ mm}$ :*

— vertex barrel double layers

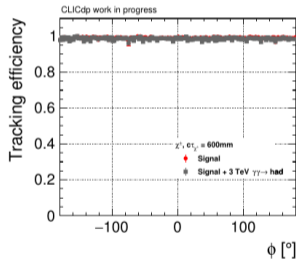

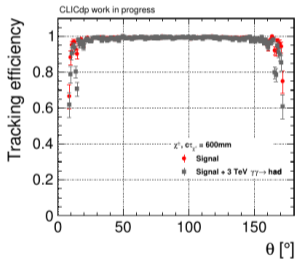

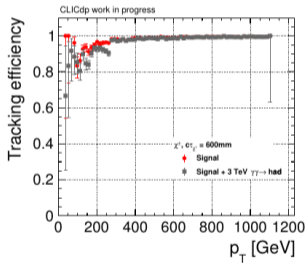

# Tracking performance

- ▶ Customized tracking validation code in place
- ▶ More details: [see Erica's slides from 01-09-2020](#)
- ▶ Chargino tracking efficiency for different lifetimes without overlay:

- ▶ Low statistics for the sample with short lifetime (6.9 mm)
- ▶ Consistent behaviour, higher tracking efficiencies for longer tracks

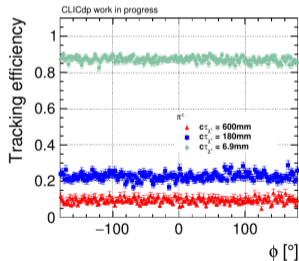

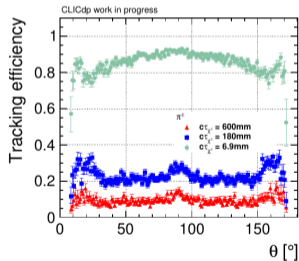

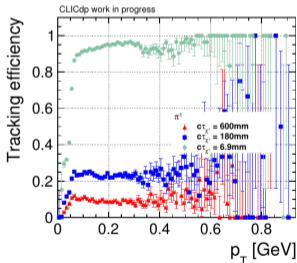

- Comparison with and without overlay shows very similar performance:

for the 600 mm sample

# Pion reconstruction and tracking performance

- ▶ Very soft pions *could* be used as an additional signature to the stub track
- ▶ Tracking efficiency highly depends on the lifetime of the chargino, i.e. the displacement of the vertex of origin of the pion

- ▶ The samples were produced with a longer lifetime than in the model
  - ▶ to ensure efficient Monte Carlo generation
  - ▶ to allow lifetime-dependent limit setting
- ▶ Use the survival probability for the chargino to travel at least the distance  $d_{min}$ :

$$P_s(d_{min}) = \frac{1}{k} e^{(-m_{\tilde{\chi}} d_{min} \Gamma_{\tilde{\chi}}) / p_{\tilde{\chi}}}$$

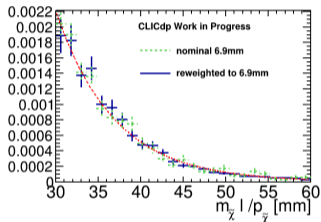

- ▶ chargino mass  $m_{\tilde{\chi}}$
- ▶ chargino momentum  $p_{\tilde{\chi}}$
- ▶ decay width  $\Gamma_{\tilde{\chi}}$
- ▶ normalization constant  $k = \frac{pc\tau}{m}$

- ▶ Resulting weights for each chargino:

$$w(\ell) = \frac{P_{target}(\ell)}{P_{MC}(\ell)} = \frac{c\tau_{MC}}{c\tau_{target}} \exp \left( -m_{\tilde{\chi}} \frac{\ell}{p_{\tilde{\chi}}} \left[ \frac{1}{c\tau_{target}} - \frac{1}{c\tau_{MC}} \right] \right)$$

applied to each event for both charginos based on truth trajectory  $\ell$

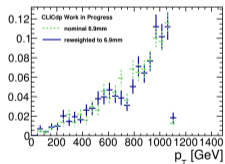

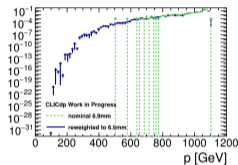

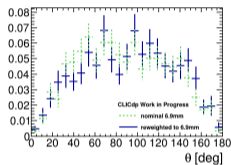

- Validate the lifetime distribution:

(both normalized to 1.0)

- statistical errors smaller for the reweighted sample for values above 30 mm (relevant range for our detector)

- Validate kinematic properties:  
( $\ell > 30$  mm to mimic detector acceptance)

- good agreement between nominal and reweighted
- validation of event-wise and pion variables good agreement as well

Charginos are pre-selected from SiTracks\_Refitted tracks with the following criteria now:

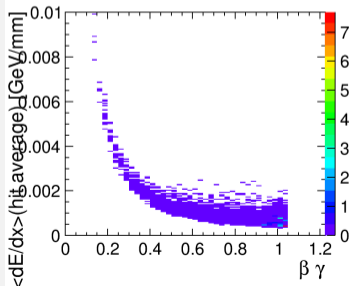

- ▶  $p_T > 1 \text{ GeV}$ ,
- ▶  $\sqrt{d_0^2 + z_0^2} < 0.5 \text{ mm}$
- ▶ if  $p_T > 1.5 \text{ GeV}$ , they should not be associated with a PFO
- ▶ isolation: the sum of the pTs of the tracks surrounding the chargino candidate track in a cone of  $R=0.1$  must not be more than 10% of the chargino candidate track pT, i.e.

$$\frac{\sum_{\text{tracks}} p_T(R \leq 0.1)}{p_T(\text{track})} < 0.1$$

The 2 preselected tracks with highest reconstructed pT are considered as chargino candidates in the event

- ▶ Study whether  $dE/dx$  can be used as a discriminating variable, possibly compensating part of the loss of sensitivity due to the limited reconstruction of  $p_T$  from tracking
- ▶  $dE/dx$  is related to  $\beta\gamma = p/m$  which is around 1 for the signal but larger for some of the backgrounds as they have smaller mass  $\rightarrow$  potential discrimination

## Average $dE/dx$ vs. $\beta\gamma$ (truth) for the highest $p_T$ chargino (after preselection):

- ▶ Cutoff at 1.02 due to the restriction of the energy to  $\sqrt{s}/2 = 1500$  GeV  $\Rightarrow$  momentum  $p < 1071$  GeV  $\Rightarrow \beta\gamma = \frac{p}{m} < 1.02$
- ▶ Compare to: (PDG)

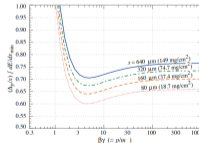

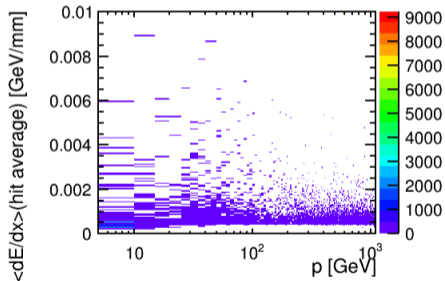

Figure 34.9: Most probable energy loss in silicon, scaled to the mean loss of a minimum ionizing particle,  $388 \text{ eV}/\mu\text{m}$  ( $1.66 \text{ MeV g}^{-1}\text{cm}^2$ ).

- ▶ Agreement with prediction

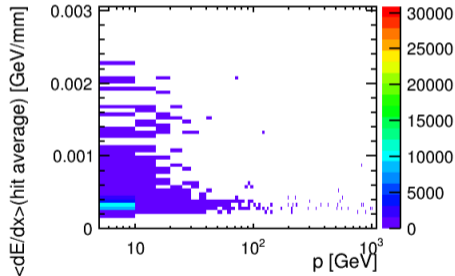

# $dE/dx$ vs reco momentum

- ▶ Average  $dE/dx$  vs reco momentum for the signal and background chargino candidates (after preselection)

ch1 (highest  $p_T$ ) in signal

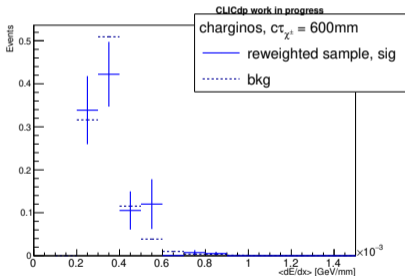

ch1 (highest  $p_T$ ) in background

- ▶ Difference between the distributions, note that the y axis ranges are quite different
- ▶ However the maximum is for both cases at low  $p_T$  and low  $dE/dx$

# dE/dx comparison and conclusions

Comparison between Signal and Background for average dE/dx:

- ▶ Fluctuations, but no clear shape difference that would allow using a cut
  - ▶ The detector acceptance introduces a bias towards more boosted particles: if  $\ell^{LF} > 30\text{ mm}$  cut is applied, this implies a cut on  $\gamma$ :  $\gamma > \frac{\ell^{RF}}{30\text{ mm}}$  (especially for low  $c\tau$ )
- ⇒ low dE/dx
- ▶ This would be different for larger p/m, i.e. smaller mass or higher  $\sqrt{s}$
- ⇒ dE/dx can still be useful for disappearing tracks in other models/parameter points

- ▶ Reweighting the 600mm sample to 6.9mm works
- ▶ New isolation variable
- ▶ Investigated  $dE/dx$  as a discriminating variable

## Outlook

- ▶ Background estimate from  $\gamma\gamma \rightarrow$  hadrons-only samples
  - ▶ shapes of distributions
  - ▶ normalization/extrapolation of total number
- ▶ Estimate sensitivity, potentially in dependence of lifetime and chargino (Higgsino) mass

# Additional Material

## ▶ production v2

- ▶ signal only: lifetime 600mm, neg.  $e^-$  beam pol, 50k events
- ▶ signal +  $\gamma\gamma \rightarrow$  hadrons background
- ▶ only  $\gamma\gamma \rightarrow$  hadrons background

## ▶ production v3

- ▶ signal only: lifetime 180mm, no  $e^-$  beam pol, 50k events

## ▶ production v4

- ▶ signal only: lifetime 6.9mm, neg.  $e^-$  polarisation, 50k events
- ▶ signal +  $\gamma\gamma \rightarrow$  hadrons background
