## Measurement prospects for di-Higgs production in the HH->bbyy channel with the ATLAS experiment at the HL-LHC

Thursday 17 March 2022 13:40 (20 minutes)

We present a prospect study on di-Higgs production in the  $HH \rightarrow b\bar{b}\gamma\gamma$  decay channel with the ATLAS experiment at the High Luminosity LHC (HL-LHC). The results are obtained by extrapolating the results from the Run 2 measurement, with 139 fb<sup>-1</sup> of data at a center-of-mass energy of 13 TeV, to the conditions expected at the HL-LHC. While there is no sign of di-Higgs production with the current LHC dataset, the much higher luminosity (3000 fb<sup>-1</sup>) and energy (14 TeV) at the HL-LHC will enable a much better measurement of this important process. We describe in detail the extrapolation process and assumptions, and multiple scenarios for the treatment of systematic uncertainties at the HL-LHC are considered. Under the baseline systematic uncertainty scenario, the extrapolated precision on the Standard Model di-Higgs signal strength measurement is 50%, corresponding to a significance of 2.2 $\sigma$ . The extrapolated precision on a measurement of  $\kappa_{\lambda}$ , the trilinear Higgs boson self-coupling modifier, is [0.3, 1.9].
