

## Structural and electronic properties of LiMnO<sub>2</sub> doped with transition metals: A first-principles study

A spin density functional study of structural and electronic properties of LiMnO<sub>2</sub> doped with different transition metals (Sc, V and Tc) is reported. The physical properties of LiMnO<sub>2</sub> material are sensitive with the transition-metal dopants. Transition metal dopants increase the lattice parameters and their volumes, thus increasing the Li diffusion channel. The computations remark that the transition metals introduce the d orbitals around the Fermi level. Tc doping in LiMnO<sub>2</sub> demonstrates the enhancement in the electronic conductivity because of the volumetric expansion. Finally, these results convey a valuable agenda for the future optimization of transition-metal doped LiMnO<sub>2</sub> cathode materials for next-generation lithium batteries.

Keywords: LiMnO<sub>2</sub>, transition metal, dope, spin density functional calculations.
