

Fully Integrated CMOS SPAD Array Sensor for Optical Fibre Readout

Peter Fischer, Robert Zimmermann
Institute for Computer Engineering, University of Heidelberg, Germany

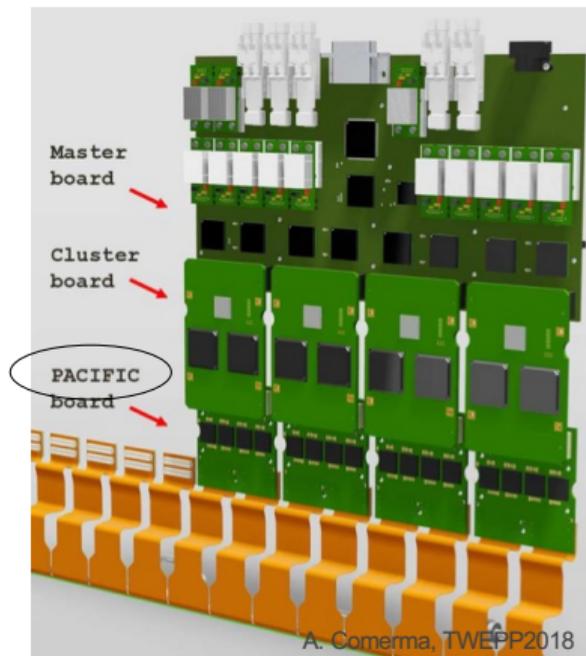

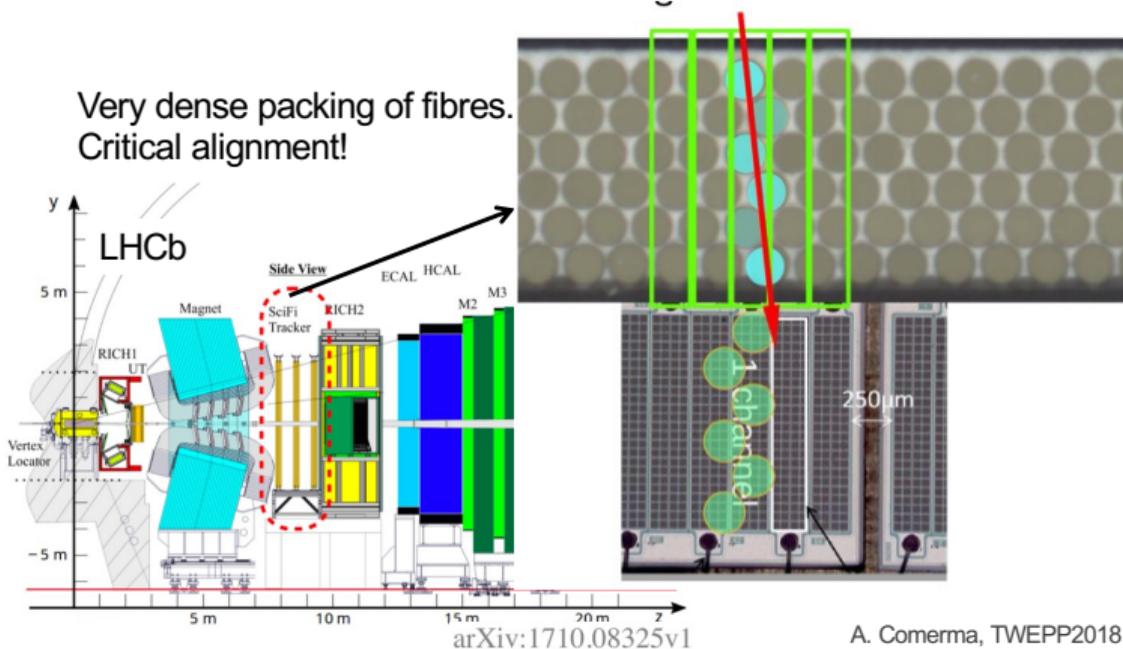

SuS@UniHD

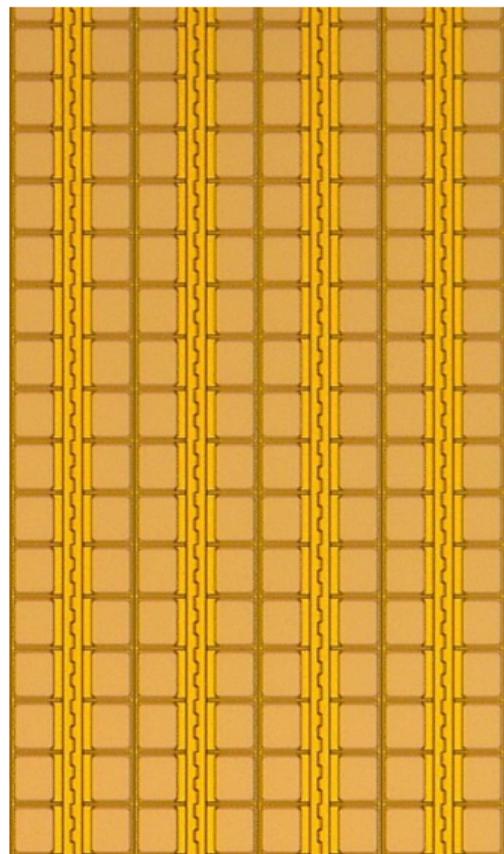

Motivation

- Some detectors place scintillating fibres in the acceptance and detect light 'outside'
- Example: 'Scintillating Fibre Tracker' of LHCb
- Light is detected with SiPM Arrays + Boards + Cables + dedicated ASICs

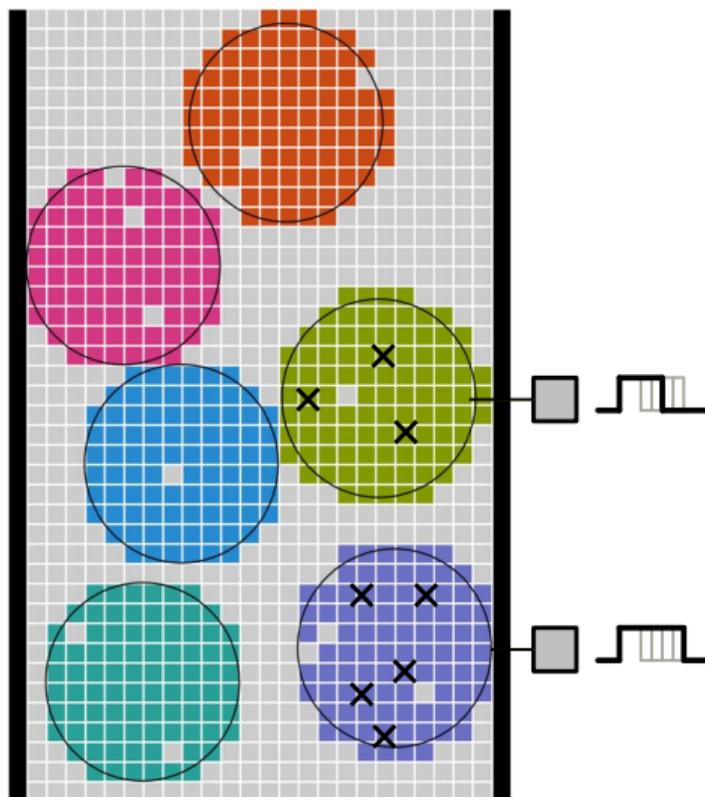

- Combine SPADs *and* CMOS circuitry on *one* chip
- Advantages (compared to ‘SiPM + ASIC’)
 - Large (‘digital’) signal per SPAD
 - → Low power
 - Can disable noisy SPADs ($\lesssim 5\%$)
 - Integrated readout architectures ! (TDC, ...)
 - Fine granular 2-D position information
 - Simple mechanics (only one component)
 - Low cost (?)
- Drawbacks
 - SPAD quality often not as good as SiPMs:
 - Higher DCR (but: can switch off noisy SPADs)
 - Lower quantum efficiency
 - Often reduced fill factor (if circuitry in pixel)

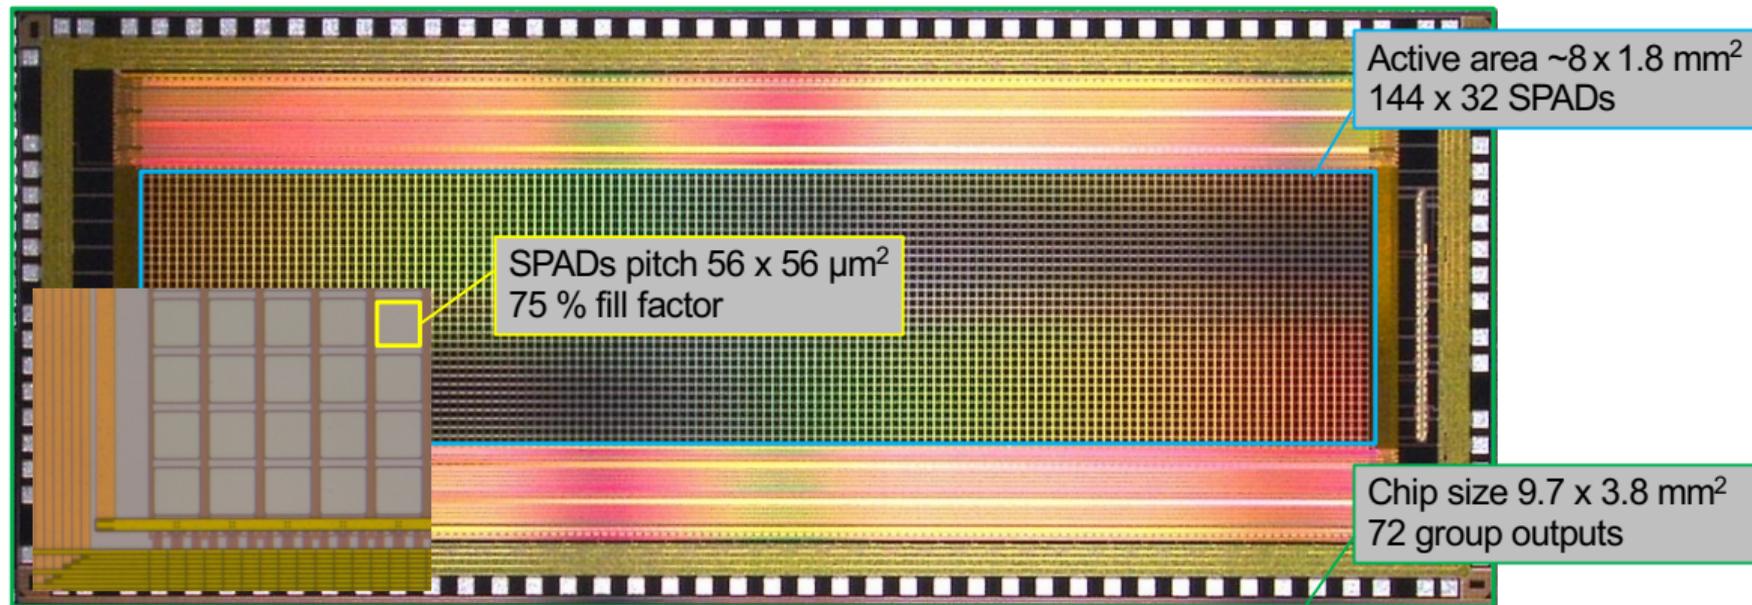

- Each SPAD can be assigned to a 'group' (= fibre)
 - Assignment is freely programmable (within limits)
 - Each 'group' is routed to a *digital* output pin
 - Number of hit SPADs is encoded in pulse width
-
- Advantages:
 - Alignment (of fibres) fully uncritical
 - No dark noise from 'unused' SPADs
 - 'Noise-free' (for small photon count)
 - Good timing (tbc)
 - Simple system with only *one* element: (sensor + readout)
 - Cheap

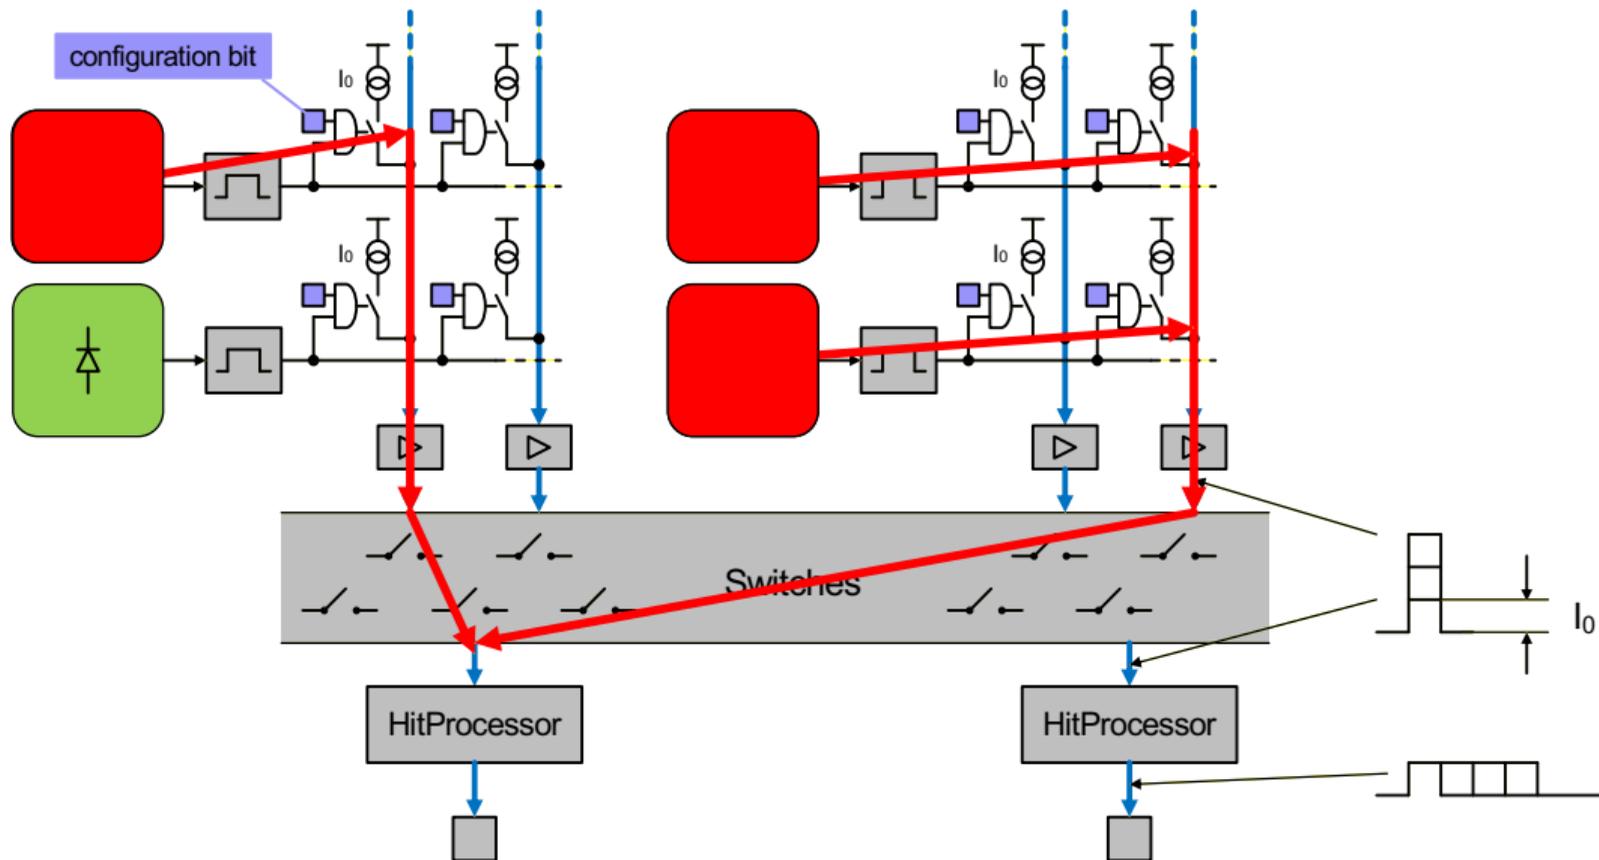

- 2 Chip versions with SPAD pitches 42/56 μm have been designed
- Chips have been produced at IMS, Duisburg (350nm, 4 metals)

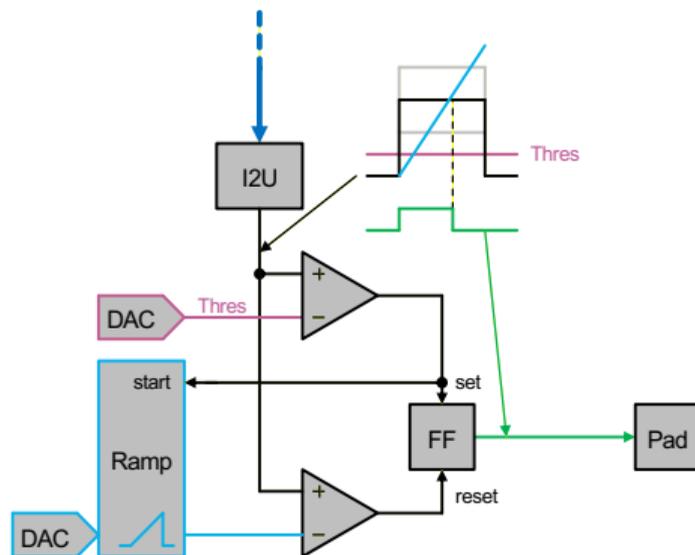

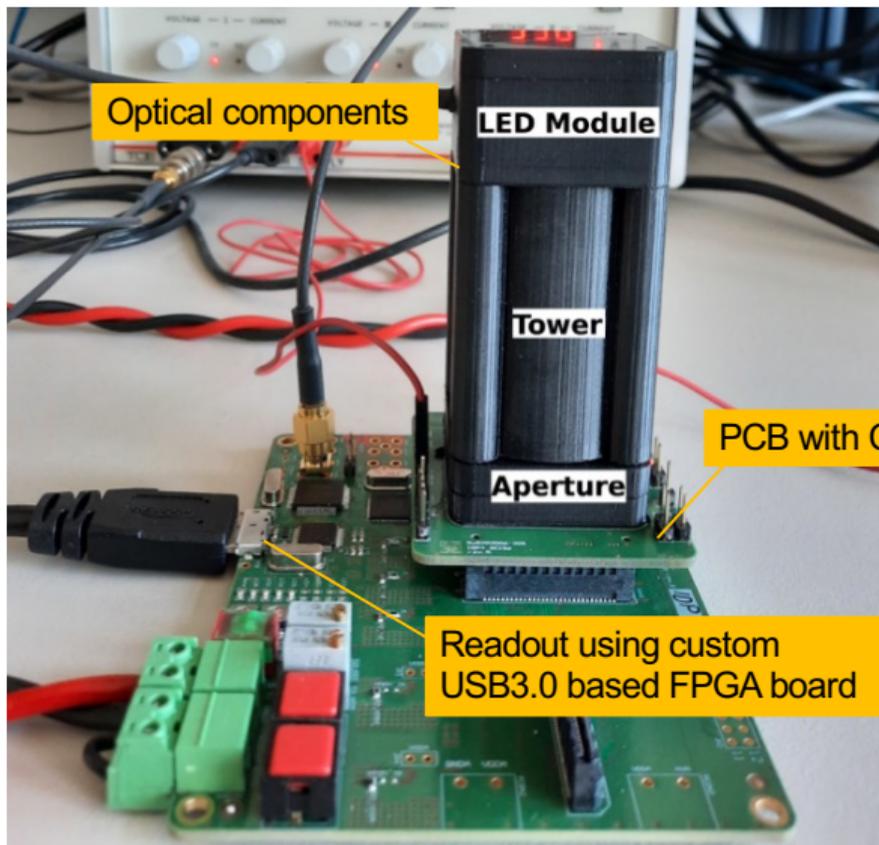

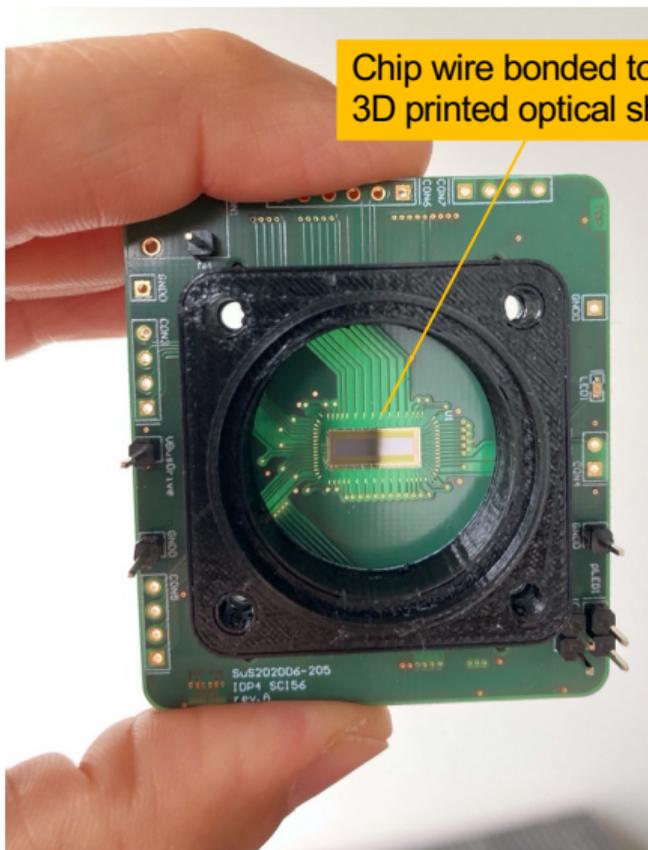

- (SCI42: 192 x 24 SPADs in 42 μm pitch, $\sim 8 \times 1 \text{ mm}^2$ sensitive area, 67% fill factor)

- Converts Multiplicity (current levels) to pulse width
- Threshold can be set to 1,2,... photons
- ΔT per bin can be set in wide range by ramp current

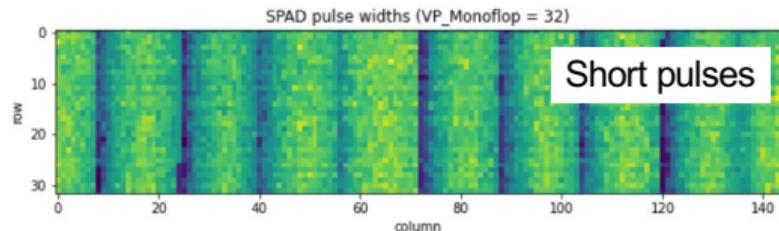

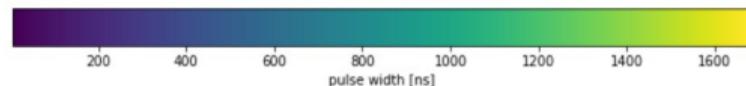

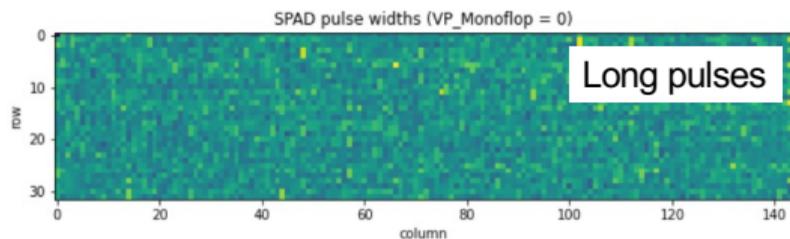

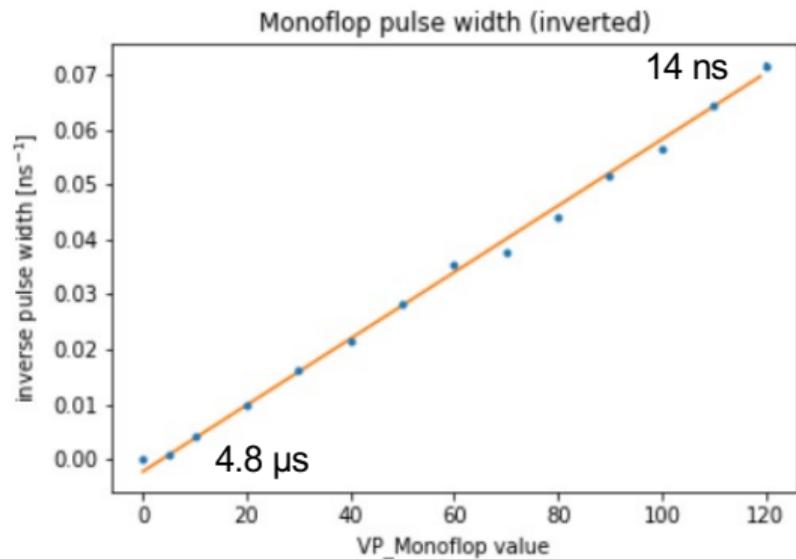

Preliminary Measurements

So far only in BSc thesis, 1 chip tested

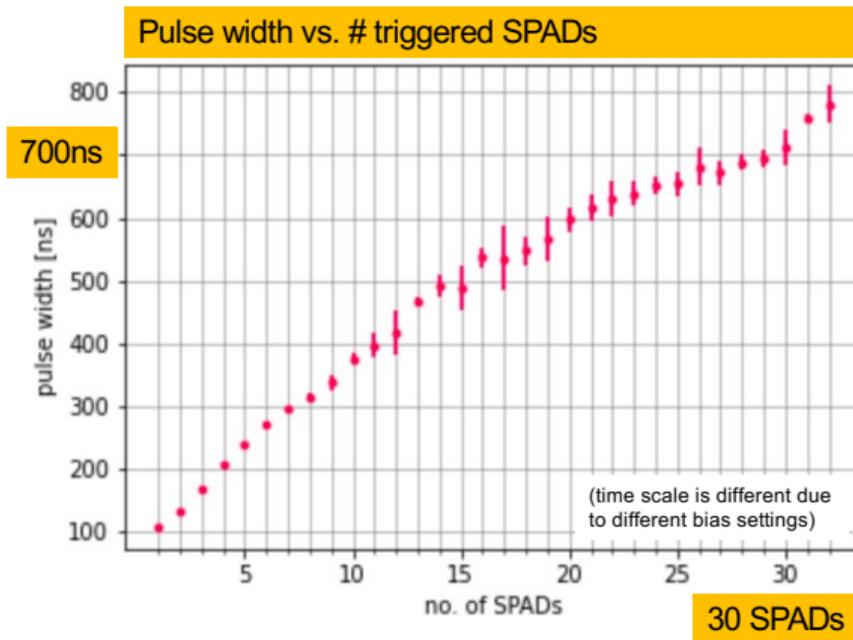

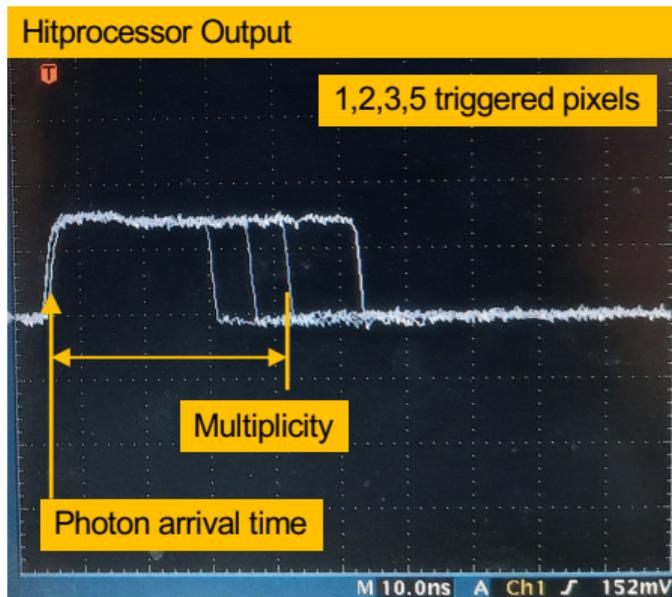

Results: Monoflop Pulse Width

- Can be varied in wide range (14ns-4.8 μ s)
- Short times show some inhomogeneities in matrix (RC time)
 - Can be improved by higher bias in buffers

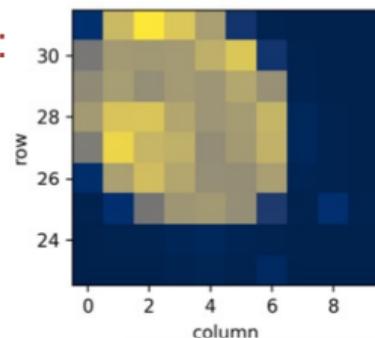

- Group Assignment and HitProcessor work! Wide range of settings.
- Multiplicities >20 can be measured. Single photon resolution for low multiplicities

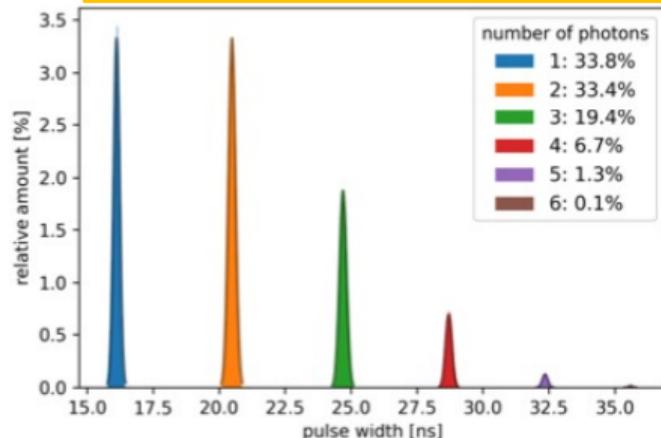

Results: Photon Multiplicities

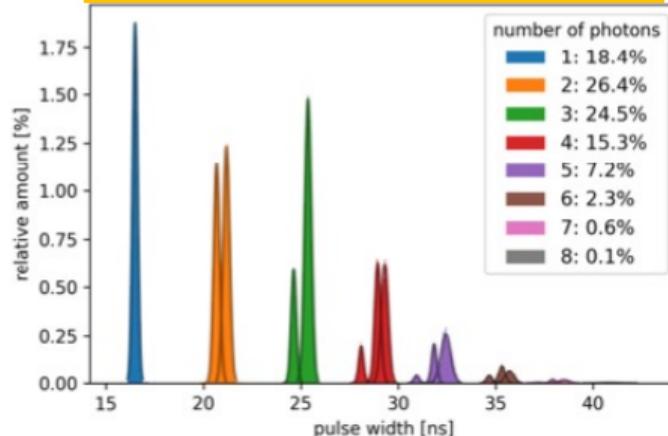

- Array is illuminated with de-focused laser spot:
- Multiplicities (from pulse width) in *one* column can be *very well* separated (left)
- When adding more columns, signals are (slightly) degraded by the switching network

Group includes only pixels in column 1:

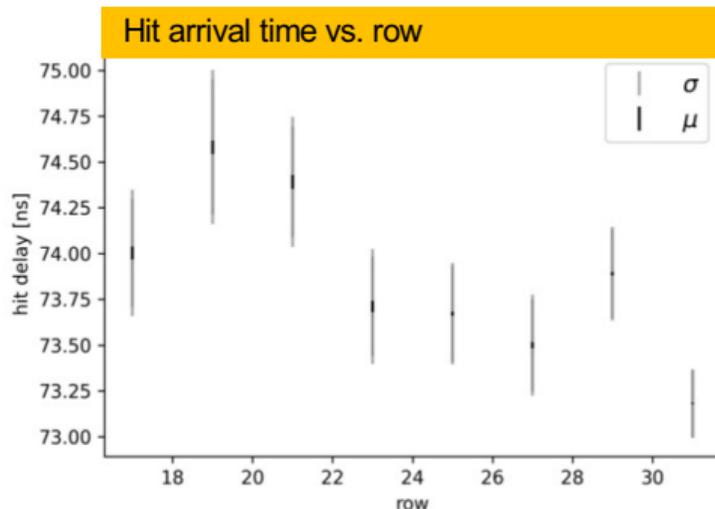

Group includes columns 0+1:

- By illuminating with a fast laser, single photon time resolution has been determined.
- For individual SPADs time resolution is $<300\text{ps}$ (probably limited by setup)

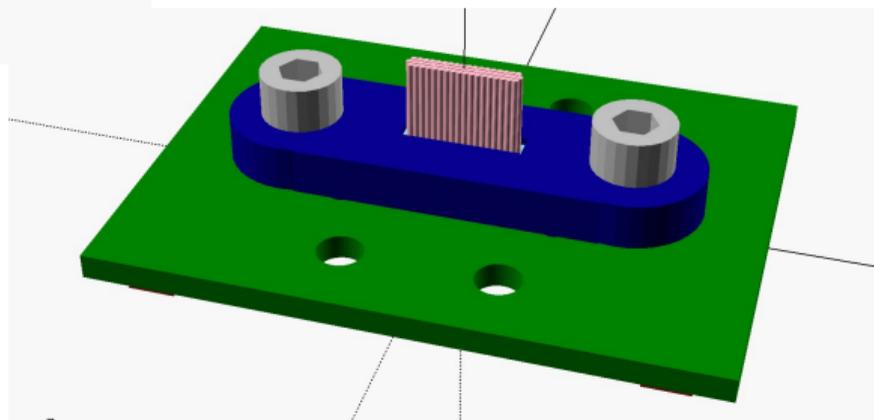

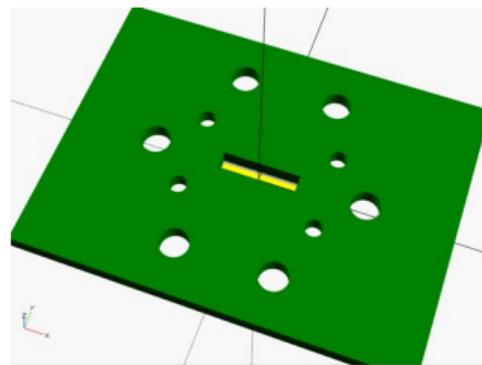

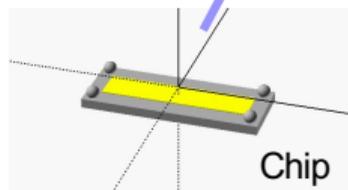

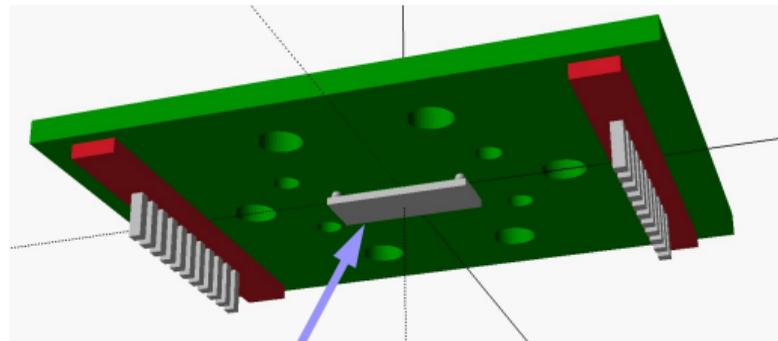

- However, systematic delays between pixels are of comparable size, and extra columns add further effects (see previous page)
 - This needs further investigation

Plans: Connecting fibres

- In 2nd iteration, will use bump bonded chip
- Fibre 'plugged' and aligned in PCB hole

- A novel CMOS SPAD architecture with group readout is proposed
- It can offer a compact, performant readout of scintillating fibres

- Two chips have been designed and produced from scratch and are fully functional
- One chip has an array of 144 x 32 SPADs of 56 μ m pitch with 75% fill factor

- A hit threshold at 1 photon is straight forward
- Robust photon counting is possible for low multiplicities
- Photon multiplicities of up to 30 have been tested (more is probably possible)
- First measurements of time resolution show position effects, but ~1ns seems feasible

- (The technology has a typical DCR of 30 kHz/mm² @ RT, max QE of 45% at 500nm)

Thank you for your attention!
