Hot Qubits on the Horizon

Wednesday, 26 May 2021 15:45 (15 minutes)

Perturbation theory for gravitating quantum systems tends to fail at very late times (a type of perturbative breakdown known as secular growth). We argue that gravity is best treated as a medium/environment in such situations, where reliable late-time predictions can be made using tools borrowed from quantum optics. To show how this works, we study the explicit example of a qubit hovering just outside the event horizon of a Schwarzschild black hole (coupled to a real scalar field) and reliably extract the late-time behaviour for the qubit state. At very late times, the so-called Unruh-DeWitt detector is shown to asymptote to a thermal state at the Hawking temperature.

Summary

This paper shows how tools from quantum optics can be potentially applied to effective field theories in order to reliably make late-time predictions (in cases when ordinary perturbation theory can fail).
