International Workshop on Future Linear Colliders, LCWS2021 March 17th, 2021

비로 (로) (로) (로) (토)

- Being the heaviest particle of the SM the top-quark is a good candidate for searching for new physics
- Its EW couplings are specially relevant in many extensions of the SM
- As the top-quark was not produced in LEP its EW sector could not be precisely measured until now
- The LHC data allows, finally, for precise measurements of this sector
- Here we present results of a global fit to top-quark EW couplings
- We used the most recent available data from the LHC (ATLAS and CMS), and also from LEP and Tevatron
- We include the QCD corrections at NLO on most of the observables used
- The fits have been performed using HEPfit [1910.14012]

・ロト ・ 早 ・ ・ ヨ ト ・ ヨ ヨ ・ クタマ

• We adopt an EFT description to parametrize the deviations from the SM.

$$\mathscr{L}_{\mathsf{eff}} = \mathscr{L}_{\mathsf{SM}} + \frac{1}{\Lambda^2} \sum_i C_i O_i + \mathscr{O}\left(\Lambda^{-4}\right).$$

- The Wilson coefficients can be later interpreted in terms of NP mediators.
- We include  $\Lambda^{-2}$  terms from the interference between the SM and D6 operators.
- We also include  $\Lambda^{-4}$  operators arising from two insertions of D6 operators.
- The effects of D8 operators, contributing to the same  $\Lambda^{-4}$  order, are omitted.

$$\sigma = \sigma_{\mathsf{SM}} + \underbrace{\frac{1}{\Lambda^2} \sum C_i O_i}_{\mathsf{SM} \times \mathsf{D6}} + \underbrace{\left(\frac{1}{\Lambda^2} \sum C_i O_i\right) \left(\frac{1}{\Lambda^2} \sum C_i O_i\right)}_{\mathsf{D6} \times \mathsf{D6}} + \underbrace{O(1/\Lambda^4)}_{\mathsf{SM} \times \mathsf{D8}}$$

- We only consider the EW two-fermion operators and ignore the imaginary parts.
- The four-fermion operators are ignored.

# Sensitivity

- The observables and coefficients in red are not included
- The  $pp \rightarrow t\bar{t}$  process is omitted in the fit in order to be consistent as it is used to reduce the dependence of  $pp \rightarrow t\bar{t}X$  on Wilson coefficients that have not been included.

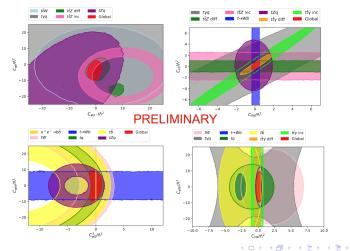

## Results - Sensitivity Individual Constraints

- Good interplay between the parameters and chosen observables
- The differential cross sections (darker regions) provide the best constraints for some observables
- LEP still generates the best constraints in some cases

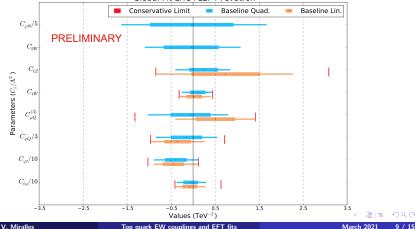

### Results - Complementarity Between Observables

- Very good complementarity between the observables
- The global fit marginalised limit is quite close to the intersection of individual fits
  - $\rightarrow$  The data set is diverse enough to avoid the existence of blind directions

# Results - Global Fit

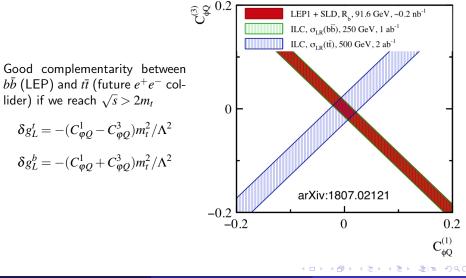

- We are able to find constraints even with the linear (only  $\Lambda^{-2}$  terms) global fit and they are similar to the ones from the quadratic ( $\Lambda^{-2} + \Lambda^{-4}$  terms) global fit for most cases
- We have checked the impact of adding estimated correlations between the observables as well as the effect of extending our basis with three more operators, the four-fermion operators  $C_x^+ = C_x^1 + C_x^2$  with x = t, b using the notation of [1807.02121], and  $C_{tG}$
- Conservative Limit: Envelope found from combining the results from all the global fits Global Fit LHC+LEP+Tevatron

- All the results are compatible with the SM with a 95% probability
- We find a reduction of the uncertainty of all the parameters of around a factor two with respect to our previous work [JHEP12(2019)098]
- Adding important correlations between the observables or even some more operators does not dramatically change the results
- LEP measurements provide tight bounds on several operators as the left-handed coupling  $C_{\varphi Q}^-$  and  $C_{\varphi Q}^{(3)}$
- The limits are extremely robust even when we only consider linear terms, except for  $C_{bW}$ ,  $C_{\varphi tb}$  and  $C_{tZ}$
- The addition of the differential cross sections of  $pp \rightarrow t\bar{t}Z$  and  $pp \rightarrow t\bar{t}\gamma$  have an important effect on  $C_{tZ}$  and  $C_{\varphi t}$
- We find the most stringent bound on top EW couplings from an EFT including all relevant 2-fermions degrees of freedom (see [JHEP 04 (2019) 100], [JHEP 02 (2020) 131], [CMS-PAS-TOP-19-001])

### Future Colliders - Complementarity on $e^+e^-$ colliders

# Future Colliders - Prospects for EW Top-Quark Couplings

- Results from [JHEP12(2019)098] show the extraordinary impact of adding the data from a  $e^+e^-$  collider working at 500 GeV  $\rightarrow$  It is crucial to go  $\sqrt{s} > 2m_t$
- The LHC Run 2 data here refers to the data available in mid 2019, with the current data the errors are reduced around a factor two

# Future Colliders - Prospects for Top-Quark+Higgs Sector

#### For current limits on this sector look at [2012.02779] and [1910.03606]

- The determination of the Higgs boson couplings at ILC250 is degraded by the additional top-quark operators
- We can recover the original bounds by the inclusion of precise measurements of top-quark EW couplings at the LHC
- The physical Higgs couplings are relatively robust, as the top mass is larger than the energy scale of EW processes
- If the ILC reaches 500 GeV it will provide very precise constraints on the top operators

# Summary

- With the current precision of the LHC we are able to constrain the top-quark EW sector even when we only consider the linear ( $\Lambda^{-2}$ ) terms
- The quadratic terms  $(\Lambda^{-4})$  are specially relevant for  $C_{bW}$  and  $C_{\varphi tb}$  whose linear dependence with our observables is zero as we are in the limit  $m_b \rightarrow 0$
- Although there is still no way for calculating the correlations between the observables it seems that they do not have a dramatic impact in the final result
- The addition of the dependence on more operators (like some four-fermion operators) does not appear to reduced the limits found significantly
- If we want to reduce the allowed ranges in some order of magnitudes it is crucial to build a  $e^+e^-$  collider working at  $\sqrt{s} > 2m_t$
- For a precise fit on the combined sector of the top plus the Higgs it would be enough with the data of a  $e^+e^-$  collider working at  $\sqrt{s} = 250$  GeV given the expected precision that the LHC could achieve for the top-quark EW couplings
