Status of heavy neutrino searches at ep colliders

Wednesday 30 June 2021 15:00 (15 minutes)

The extension of the SM of particle physics by sterile neutrinos explains the smallness of neutrino masses as observed by the neutrino oscillation experiment. Since the mass scale of the sterile neutrinos is unconstrained, it is useful to discuss experimental motivated predictions for specific mass scale. Sterile neutrinos can be tested at particle colliders in three different mass ranges

$M_N < M_W$, where the sterile neutrinos can be long lived and can be tested via its displaced distance.

$M_N \sim E_W$ scale; around this mass scale the sterile neutrinos can be tested via lepton number or lepton flavor violation processes.

$M_N > O(\text{TeV})$; sterile neutrinos can be tested indirectly via its contribution to loop processes, e.g. $Z \rightarrow \mu e$, $\mu \rightarrow 3e$, etc.

In this talk, we investigate the sensitivity of the proposed Large Hadron Electron collider (LHeC) and the Future Circular Collider (FCCeh) to sterile neutrino searches for the three mass scales.
